

Package ‘httk’

September 8, 2022

Version 2.2.0

Date 2022-08-22

Title High-Throughput Toxicokinetics

Description Pre-made models that can be rapidly tailored to various chemicals and species using chemical-specific in vitro data and physiological information. These tools allow incorporation of chemical toxicokinetics (‘‘TK”) and in vitro-in vivo extrapolation (‘‘IVIVE”) into bioinformatics, as described by Pearce et al. (2017) (<[doi:10.18637/jss.v079.i04](https://doi.org/10.18637/jss.v079.i04)>). Chemical-specific in vitro data characterizing toxicokinetics can be obtained from relatively high-throughput experiments. The chemical-independent (‘‘generic”) physiologically-based (‘‘PBTK”) and empirical (for example, one compartment) ‘‘TK” models included here can be parameterized with in vitro data or in silico predictions which are provided for thousands of chemicals, multiple exposure routes, and various species. The models are systems of ordinary differential equations that are solved using compiled (C-based) code for speed. A Monte Carlo sampler is included for simulating human biological variability (Ring et al., 2017 <[doi:10.1016/j.envint.2017.06.004](https://doi.org/10.1016/j.envint.2017.06.004)>) and propagating parameter uncertainty (Wambaugh et al., 2019 <[doi:10.1093/toxsci/kfz205](https://doi.org/10.1093/toxsci/kfz205)>). Empirically calibrated methods are included for predicting tissue:plasma partition coefficients and volume of distribution (Pearce et al., 2017 <[doi:10.1007/s10928-017-9548-7](https://doi.org/10.1007/s10928-017-9548-7)>). These functions and data provide a set of tools for using IVIVE to convert concentrations from high-throughput screening experiments (for example, Tox21, ToxCast) to real-world exposures via reverse dosimetry (also known as ‘‘RTK”) (Wetmore et al., 2015 <[doi:10.1093/toxsci/kfv171](https://doi.org/10.1093/toxsci/kfv171)>).

Description

Pre-made models that can be rapidly tailored to various chemicals and species using chemical-specific in vitro data and physiological information. These tools allow incorporation of chemical toxicokinetics ("TK") and in vitro-in vivo extrapolation ("IVIVE") into bioinformatics, as described by Pearce et al. (2017) (<doi:10.18637/jss.v079.i04>). Chemical-specific in vitro data characterizing toxicokinetics can be obtained from relatively high-throughput experiments. The chemical-independent ("generic") physiologically-based ("PBTK") and empirical (for example, one compartment) "TK" models included here can be parameterized with in vitro data or in silico predictions which are provided for thousands of chemicals, multiple exposure routes, and various species. The models are systems of ordinary differential equations that are solved using compiled (C-based) code for speed. A Monte Carlo sampler is included for simulating human biological variability (Ring et al., 2017 <doi:10.1016/j.envint.2017.06.004>) and propagating parameter uncertainty (Wambaugh et al., 2019 <doi:10.1093/toxsci/kfz205>). Empirically calibrated methods are included for predicting tissue:plasma partition coefficients and volume of distribution (Pearce et al., 2017 <doi:10.1007/s10928-017-9548-7>). These functions and data provide a set of tools for using IVIVE to convert concentrations from high-throughput screening experiments (for example, Tox21, ToxCast) to real-world exposures via reverse dosimetry (also known as "RTK") (Wetmore et al., 2015 <doi:10.1093/toxsci/kfv171>).

add_chemtable

Add a table of chemical information for use in making htk predictions.

Description

This function adds chemical-specific information to the table `chem.physical_and_invitro.data`. This table is queried by the model parameterization functions when attempting to parameterize a model, so adding sufficient data to this table allows additional chemicals to be modeled.

Usage

```
add_chemtable(
  new.table,
  data.list,
  current.table = NULL,
  reference = NULL,
  species = NULL,
  overwrite = FALSE,
  sig.fig = 4,
  clint.pvalue.overwrite = TRUE,
  allow.na = FALSE
)
```

Arguments

<code>new.table</code>	Object of class <code>data.frame</code> containing one row per chemical, with each chemical minimally described by a CAS number.
<code>data.list</code>	This list identifies which properties are to be read from the table. Each item in the list should point to a column in the table <code>new.table</code> . Valid names in the list are: <code>'Compound'</code> , <code>'CAS'</code> , <code>'DSSTox.GSID'</code> , <code>'SMILES.desalt'</code> , <code>'Reference'</code> , <code>'Species'</code> , <code>'MW'</code> , <code>'logP'</code> , <code>'pKa_Donor'</code> , <code>'pKa_Accept'</code> , <code>'logMA'</code> , <code>'Clint'</code> , <code>'Clint.pValue'</code> , <code>'Funbound.plasma'</code> , <code>'Fgutabs'</code> , <code>'Rblood2plasma'</code> .
<code>current.table</code>	This is the table to which data are being added.
<code>reference</code>	This is the reference for the data in the new table. This may be omitted if a column in <code>data.list</code> gives the reference value for each chemical.
<code>species</code>	This is the species for the data in the new table. This may be omitted if a column in <code>data.list</code> gives the species value for each chemical or if the data are not species-specific (e.g., MW).

overwrite	If overwrite=TRUE then data in current.table will be replaced by any data in new.table that is for the same chemical and property. If overwrite=FALSE (DEFAULT) then new data for the same chemical and property are ignored. Funbound.plasma values of 0 (below limit of detection) are overwritten either way.
sig.fig	Sets the number of significant figures stored (defaults to 4)
clint.pvalue.overwrite	If TRUE then the CL_int p-value is set to NA when the CL_int value is changed unless a new p-value is provided. (defaults to TRUE)
allow.na	If TRUE (default is FALSE) then NA values are written to the table, otherwise they are ignored.

Value

data.frame A new data.frame containing the data in current.table augmented by new.table

Author(s)

John Wambaugh

Examples

```
library(httk)
my.new.data <- as.data.frame(c("A", "B", "C"), stringsAsFactors=FALSE)
my.new.data <- cbind(my.new.data, as.data.frame(c(
  "111-11-2", "222-22-0", "333-33-5"),
  stringsAsFactors=FALSE))
my.new.data <- cbind(my.new.data, as.data.frame(c("DTX1", "DTX2", "DTX3"),
  stringsAsFactors=FALSE))
my.new.data <- cbind(my.new.data, as.data.frame(c(200, 200, 200)))
my.new.data <- cbind(my.new.data, as.data.frame(c(2, 3, 4)))
my.new.data <- cbind(my.new.data, as.data.frame(c(0.01, 0.02, 0.3)))
my.new.data <- cbind(my.new.data, as.data.frame(c(0, 10, 100)))

pKa_Accept="pka.b"),
species="Human",
reference="MyPaper 2015")

# Note that average and max change (relative to above):
calc_css(chem.name="B")

```

age_draw_smooth	<i>Draws ages from a smoothed distribution for a given gender/race combination</i>
-----------------	--

Description

This function should usually not be called directly by the user. It is used by `httkpop_generate()` in "virtual-individuals" mode.

Usage

```
age_draw_smooth(gender, reth, nsamp, agelim_months, nhanes_mec_svy)
```

Arguments

gender	Gender. Either 'Male' or 'Female'.
reth	Race/ethnicity. One of 'Mexican American', 'Other Hispanic', 'Non-Hispanic Black', 'Non-Hispanic White', 'Other'.
nsamp	Number of ages to draw.
agelim_months	Two-element numeric vector giving the minimum and maximum ages in months to include.
nhanes_mec_svy	surveydesign object created from <code>mecdt</code> using <code>svydesign</code> (this is done in <code>httkpop_generate</code>)

Value

A named list with members 'ages_months' and 'ages_years', each numeric of length nsamp, giving the sampled ages in months and years.

armitage_estimate_sarea

Estimate well surface area

Description

Estimate geometry surface area of plastic in well plate based on well plate format suggested values from Corning. option.plastic == TRUE (default) give nonzero surface area (sarea, m²) option.bottom == TRUE (default) includes surface area of the bottom of the well in determining sarea. Optionally include user values for working volume (v_working, m³) and surface area.

Usage

```
armitage_estimate_sarea(
  tcdata = NA,
  this.well_number = 384,
  this.cell_yield = NA,
  this.v_working = NA
)
```

Arguments

tcdata	A data table with well_number corresponding to plate format, optionally include v_working, sarea, option.bottom, and option.plastic
this.well_number	For single value, plate format default is 384, used if is.na(tcdata)==TRUE
this.cell_yield	For single value, optionally supply cell_yield, otherwise estimated based on well number
this.v_working	For single value, optionally supply working volume, otherwise estimated based on well number (m ³)

Value

A data table composed of any input data.table *tcdata* with only the following columns either created or altered by this function:

Column Name	Description	Units
well_number	number of wells on plate	
sarea	surface area	m ²
cell_yield	number of cells	cells
v_working	working (filled) volume of each well	uL
v_total	total volume of each well	uL

Author(s)

armitage_eval	<i>Evaluate the updated Armitage model</i>
---------------	--

Description

Evaluate the Armitage model for chemical distribution in vitro. Takes input as data table or vectors of values. Outputs a data table. Updates over the model published in Armitage et al. 2014 include binding to plastic walls and lipid and protein compartments in cells.

Usage

```
armitage_eval(
  casrn.vector = NA_character_,
  nomconc.vector = 1,
  this.well_number = 384,
  this.FBSf = NA_real_,
  tcdata = NA,
  this.sarea = NA_real_,
  this.v_total = NA_real_,
  this.v_working = NA_real_,
  this.cell_yield = NA_real_,
  this.Tsys = 37,
  this.Tref = 298.15,
  this.option.kbsa2 = FALSE,
  this.option.swat2 = FALSE,
  this.pseudooct = 0.01,
  this.memblip = 0.04,
  this.nlom = 0.2,
  this.P_nlom = 0.035,
  this.P_dom = 0.05,
  this.P_cells = 1,
  this.csalt = 0.15,
  this.celldensity = 1,
```

```

    this.cellmass = 3,
    this.f_oc = 1,
    this.conc_ser_alb = 24,
    this.conc_ser_lip = 1.9,
    this.Vdom = 0
)

```

Arguments

<code>casrn.vector</code>	For vector or single value, CAS number
<code>nomconc.vector</code>	For vector or single value, micromolar nominal concentration (e.g. AC50 value)
<code>this.well_number</code>	For single value, plate format default is 384, used if <code>is.na(tcdata)==TRUE</code>
<code>this.FBSf</code>	Fraction fetal bovine serum, must be entered by user.
<code>tcdata</code>	A <code>data.table</code> with <code>casrn</code> , <code>nomconc</code> , <code>MP</code> , <code>gkpw</code> , <code>gkaw</code> , <code>gswat</code> , <code>sarea</code> , <code>v_total</code> , <code>v_working</code> . Otherwise supply single values to <code>this.params</code> .
<code>this.sarea</code>	Surface area per well (m ²)
<code>this.v_total</code>	Total volume per well (m ³)
<code>this.v_working</code>	Working volume per well (m ³)
<code>this.cell_yield</code>	Number of cells per well
<code>this.Tsys</code>	System temperature (degrees C)
<code>this.Tref</code>	Reference temperature (degrees K)
<code>this.option.kbsa2</code>	Use alternative bovine-serum-albumin partitioning model
<code>this.option.swat2</code>	Use alternative water solubility correction
<code>this.pseudooct</code>	Pseudo-octanol cell storage lipid content
<code>this.memblip</code>	Membrane lipid content of cells
<code>this.nlom</code>	Structural protein content of cells
<code>this.P_nlom</code>	Proportionality constant to octanol structural protein
<code>this.P_dom</code>	Proportionality constant to dissolve organic material
<code>this.P_cells</code>	Proportionality constant to octanol storage lipid
<code>this.csalt</code>	Ionic strength of buffer, mol/L
<code>this.celldensity</code>	Cell density kg/L, g/mL
<code>this.cellmass</code>	Mass per cell, ng/cell
<code>this.f_oc</code>	1, everything assumed to be like proteins
<code>this.conc_ser_alb</code>	24 g/L, mass concentration of albumin in serum.
<code>this.conc_ser_lip</code>	1.9 g/L, mass concentration of lipids in serum.
<code>this.Vdom</code>	0 ml, the volume of dissolved organic matter (DOM)

Value

Column	Description	units
casrn	Chemical Abstracts Service Registry Number	
nomconc	Nominal Concentration	mol/L
well_number	Number of wells in plate	unitless
sarea	Surface area of well	m ²
v_total	Total volume of well	m ³
v_working	Filled volume of well	m ³
cell_yield	Number of cells	cells
gkow	log10 octanol to water partition coefficient (PC)	log10
logHenry	log10 Henry's law constant '	log10 atm-m ³ /mol
gswat	log10 Water solubility	log10 mol/L
MP	Melting Point	degrees Celsius
MW	Molecular Weight	g/mol
gkaw	air-water partition coefficient	(mol/m ³)/(mol/m ³)

augment.table	Add a parameter value to the chem.physical_and_invitro.data table
---------------	---

Description

This internal function is used by [add_chemtable](#) to add a single new parameter to the table of chemical parameters. It should not be typically used from the command line.

Usage

```
augment.table(  
  this.table,  
  this.CAS,  
  compound.name = NULL,  
  this.property,  
  value,  
  species = NULL,  
  reference,  
  overwrite = FALSE,  
  sig.fig = 4,  
  clint.pvalue.overwrite = TRUE,  
  allow.na = FALSE  
)
```

Arguments

this.table	Object of class data.frame containing one row per chemical.
this.CAS	The Chemical Abstracts Service registry number (CAS-RN) corresponding to the parameter value
compound.name	A name associated with the chemical (defaults to NULL)
this.property	The property being added/modified.
value	The value being assigned to this.property.
species	This is the species for the data in the new table. This may be omitted if a column in data.list gives the species value for each chemical or if the data are not species-specific (e.g., MW).
reference	This is the reference for the data in the new table. This may be omitted if a column in data.list gives the reference value for each chemical.
overwrite	If overwrite=TRUE then data in current.table will be replaced by any data in new.table that is for the same chemical and property. If overwrite=FALSE (DEFAULT) then new data for the same chemical and property are ignored. Fun-bound.plasma values of 0 (below limit of detection) are overwritten either way.
sig.fig	Sets the number of significant figures stored (defaults to 4)
clint.pvalue.overwrite	If TRUE then the CI_int p-value is set to NA when the CI_int value is changed unless a new p-value is provided. (defaults to TRUE)
allow.na	If TRUE (default is FALSE) then NA values are written to the table, otherwise they are ignored.

Value

`data.frame` A new `data.frame` containing the data in `current.table` augmented by `new.table`

Author(s)

John Wambaugh

`available_rblood2plasma`

Find the best available ratio of the blood to plasma concentration constant.

Description

This function finds the best available constant ratio of the blood concentration to the plasma concentration, using `get_rblood2plasma` and `calc_rblood2plasma`.

Usage

```
available_rblood2plasma(
  chem.cas = NULL,
  chem.name = NULL,
  dtxsid = NULL,
  species = "Human",
  adjusted.funbound.plasma = TRUE,
  suppress.messages = FALSE
)
```

Arguments

<code>chem.cas</code>	Either the CAS number or the chemical name must be specified.
<code>chem.name</code>	Either the chemical name or the CAS number must be specified.
<code>dtxsid</code>	EPA's 'DSSTox Structure ID (https://comptox.epa.gov/dashboard) the chemical must be identified by either CAS, name, or DTXSIDs
<code>species</code>	Species desired (either "Rat", "Rabbit", "Dog", "Mouse", or default "Human").
<code>adjusted.funbound.plasma</code>	Whether or not to use <code>Funbound.plasma</code> adjustment if calculating <code>Rblood2plasma</code> .
<code>suppress.messages</code>	Whether or not to display relevant warning messages to user.

Details

Either retrieves a measured blood:plasma concentration ratio from the `chem.physical_and_invitro.data` table or calculates it using the red blood cell partition coefficient predicted with Schmitt's method

If available, in vivo data (from `chem.physical_and_invitro.data`) for the given species is returned, substituting the human in vivo value when missing for other species. In the absence of in vivo data, the value is calculated with `calc_rblood2plasma` for the given species. If `Funbound.plasma` is unavailable for the given species, the human `Funbound.plasma` is substituted. If none of these are available, the mean human `Rblood2plasma` from `chem.physical_and_invitro.data` is returned. details than the description above ~~

Value

The blood to plasma chemical concentration ratio – measured if available, calculated if not.

Author(s)

Robert Pearce

Examples

```
available_rblood2plasma(chem.name="Bisphenol A",adjusted.funbound.plasma=FALSE)
available_rblood2plasma(chem.name="Bisphenol A",species="Rat")
```

aylward2014

Aylward et al. 2014

Description

Aylward et al. (2014) compiled measurements of the ratio of maternal to fetal cord blood chemical concentrations at birth for a range of chemicals with environmental routes of exposure, including bromodiphenyl ethers, fluorinated compounds, organochlorine pesticides, polyaromatic hydrocarbons, tobacco smoke components, and vitamins.

Usage

```
aylward2014
```

Format

data.frame

Source

Kapraun et al. 2021 (submitted)

References

Aylward LL, Hays SM, Kirman CR, Marchitti SA, Kenneke JF, English C, Mattison DR, Becker RA (2014). blood_mass_correct	<i>Find average blood masses by age.</i>
--------------------	--

Description

If blood mass from `blood_weight` is negative or very small, then just default to the mean blood mass by age. (Geigy Scientific Tables, 7th ed.)

Usage

```
blood_mass_correct(blood_mass, age_months, age_years, gender, weight)
```

Arguments

blood_mass	A vector of blood masses in kg to be replaced with averages.
age_months	A vector of ages in months.
age_years	A vector of ages in years.
gender	A vector of genders (either 'Male' or 'Female').
weight	A vector of body weights in kg.

Value

A vector of blood masses in kg.

Author(s)

Caroline Ring

References

blood_weight	<i>Predict blood mass.</i>
--------------	----------------------------

Description

Predict blood mass based on body surface area and gender, using equations from Bosgra et al. 2012

Usage

```
blood_weight(BSA, gender)
```

Arguments

BSA	Body surface area in m ² . May be a vector.
gender	Either 'Male' or 'Female'. May be a vector.

Value

A vector of blood masses in kg the same length as BSA and gender.

Author(s)

Caroline Ring

bmiage

CDC BMI-for-age charts

Description

Charts giving the BMI-for-age percentiles for boys and girls ages 2-18

Usage

bmiage

Format

A data.table with 434 rows and 5 variables:

Sex Female or Male

Agemos Age in months

P5 The 5th percentile BMI for the corresponding sex and age

P85 The 85th percentile BMI for the corresponding sex and age

P95 The 95th percentile BMI for the corresponding sex and age

Details

For children ages 2 to 18, weight class depends on the BMI-for-age percentile.

Underweight <5th percentile

Normal weight 5th-85th percentile

Overweight 85th-95th percentile

Obese >=95th percentile

body_surface_area	<i>Predict body surface area.</i>
-------------------	-----------------------------------

Description

Predict body surface area from weight, height, and age, using Mosteller's formula for age>18 and Haycock's formula for age<18

Usage

```
body_surface_area(BW, H, age_years)
```

Arguments

BW	A vector of body weights in kg.
H	A vector of heights in cm.
age_years	A vector of ages in years.

Value

A vector of body surface areas in cm².

Author(s)

Caroline Ring

bone_mass_age	<i>Predict bone mass</i>
---------------	--------------------------

Description

Predict bone mass from age_years, height, weight, gender, using logistic equations fit to data from Baxter-Jones et al. 2011, or for infants < 1 year, using equation from Koo et al. 2000 (See Price et al. 2003)

Usage

```
bone_mass_age(age_years, age_months, height, weight, gender)
```

Arguments

age_years	Vector of ages in years.
age_months	Vector of ages in months.
height	Vector of heights in cm.
weight	Vector of body weights in kg.
gender	Vector of genders, either 'Male' or 'Female'.

Value

Vector of bone masses.

brain_mass	<i>Predict brain mass.</i>
------------	----------------------------

Description

Predict brain mass from gender and age.

Usage

```
brain_mass(gender, age_years)
```

Arguments

gender	Vector of genders, either 'Male' or 'Female'
age_years	Vector of ages in years.

Value

A vector of brain masses in kg.

Author(s)

Caroline Ring

calc_analytic_css	<i>Calculate the analytic steady state plasma concentration.</i>
-------------------	--

Description

This function calculates the analytic steady state plasma or venous blood concentrations as a result of infusion dosing for the three compartment and multiple compartment PBTK models.

Usage

```
calc_analytic_css(  
  chem.name = NULL,  
  chem.cas = NULL,  
  dtxsid = NULL,  
  parameters = NULL,  
  species = "human",  
  daily.dose = 1,  
  route = "oral",  
  exp.conc = 1,  
  period = 24,  
  exp.duration = 24,
```

```

    output.units = "uM",
    model = "pbtk",
    concentration = "plasma",
    suppress.messages = FALSE,
    tissue = NULL,
    restrictive.clearance = TRUE,
    bioactive.free.invivo = FALSE,
    IVIVE = NULL,
    parameterize.args = list(),
    ...
)

```

Arguments

chem.name	Either the chemical name, CAS number, or the parameters must be specified.
chem.cas	Either the chemical name, CAS number, or the parameters must be specified.
dtxsid	EPA's DSSTox Structure ID (https://comptox.epa.gov/dashboard) the chemical must be identified by either CAS, name, or DTXSIDs
parameters	Chemical parameters from parameterize_pbtk (for model = 'pbtk'), parameterize_3comp (for model = '3compartment'), parameterize_1comp (for model = '1compartment') or parameterize_steadystate (for model = '3compartmentss'), overrides chem.name and chem.cas.
species	Species desired (either "Rat", "Rabbit", "Dog", "Mouse", or default "Human").
daily.dose	Total daily dose, mg/kg BW.
route	Route of exposure (either "oral", "iv", or "inhalation" default "oral").
exp.conc	Specified inhalation exposure concentration for use in assembling 'forcings' data series argument for integrator. Defaults to uM/L
period	For use in assembling forcing function data series 'forcings' argument, specified in hours
exp.duration	For use in assembling forcing function data series 'forcings' argument, specified in hours
output.units	Units for returned concentrations, defaults to uM (specify units = "uM") but can also be mg/L.
model	Model used in calculation, 'gas_pbtk' for the gas pbtk model, 'pbtk' for the multiple compartment model, '3compartment' for the three compartment model, '3compartmentss' for the three compartment steady state model, and '1compartment' for one compartment model.
concentration	Desired concentration type: 'blood', 'tissue', or default 'plasma'. In the case that the concentration is for plasma, selecting "blood" will use the blood:plasma ratio to estimate blood concentration. In the case that the argument 'tissue' specifies a particular tissue of the body, concentration defaults to 'tissue' – that is, the concentration in the If cocentration is set to 'blood' or 'plasma' and 'tissue' specifies a specific tissue then the value returned is for the plasma or blood in that specific tissue.
suppress.messages	Whether or not the output message is suppressed.
tissue	Desired steady state tissue concentration. Default is of NULL typically gives whole body plasma concentration.

restrictive.clearance	If TRUE (default), then only the fraction of chemical not bound to protein is available for metabolism in the liver. If FALSE, then all chemical in the liver is metabolized (faster metabolism due to rapid off-binding).
bioactive.free.invivo	If FALSE (default), then the total concentration is treated as bioactive in vivo. If TRUE, the the unbound (free) plasma concentration is treated as bioactive in vivo. Only works with tissue = NULL in current implementation.
IVIVE	Honda et al. (2019) identified four plausible sets of assumptions for <i>in vitro-in vivo</i> extrapolation (IVIVE) assumptions. Argument may be set to "Honda1" through "Honda4". If used, this function overwrites the tissue, restrictive.clearance, and bioactive.free.invivo arguments. See Details below for more information.
parameterize.args	List of arguments passed to model's associated parameterization function, including default.to.human, adjusted.Funbound.plasma, regression, and minimum.Funbound.plasma. The default.to.human argument substitutes missing animal values with human values if true, adjusted.Funbound.plasma returns adjusted Funbound.plasma when set to TRUE along with partition coefficients calculated with this value, regression indicates whether or not to use the regressions in calculating partition coefficients, and minimum.Funbound.plasma is the value to which Monte Carlo draws less than this value are set (default is 0.0001 – half the lowest measured Fup in our dataset).
...	Additional parameters passed to parameterize function if parameters is NULL.

Details

Concentrations are calculated for the specified model with constant oral infusion dosing. All tissues other than gut, liver, and lung are the product of the steady state plasma concentration and the tissue to plasma partition coefficient.

	<i>in vivo</i> Conc.	Metabolic Clearance	Bioactive Chemical Conc.	TK Statistic Used*
Honda1	Veinous (Plasma)	Restrictive	Free	Mean Conc.
Honda2	Veinous	Restrictive	Free	Max Conc.
Honda3	Veinous	Non-restrictive	Total	Mean Conc.
Honda4	Veinous	Non-restrictive	Total	Max Conc.
Honda5	Target Tissue	Non-restrictive	Total	Mean Conc.
Honda6	Target Tissue	Non-restrictive	Total	Max Conc.

*Assumption is currently ignored because analytical steady-state solutions are currently used by this function.

Value

Steady state plasma concentration in specified units

Author(s)

Robert Pearce, John Wambaugh, Greg Honda, Miyuki Breen

References

Examples

```
calc_analytic_css(chem.name='Bisphenol-A',output.units='mg/L',
                  model='3compartment',concentration='blood')

calc_analytic_css(chem.name='Bisphenol-A',tissue='liver',species='rabbit',
                  parameterize.args = list(
                    default.to.human=TRUE,
                    adjusted.funbound.plasma=TRUE,
                    regression=TRUE,
                    minimum.funbound.plasma=1e-4),daily.dose=2)

calc_analytic_css(chem.name="bisphenol a",model="1compartment")

calc_analytic_css(chem.cas="80-05-7",model="3compartmentss")

params <- parameterize_pbt(chem.cas="80-05-7")

calc_analytic_css(parameters=params,model="pbt")
```

calc_analytic_css_1comp

Calculate the analytic steady state concentration for the one compartment model.

Description

This function calculates the analytic steady state plasma or venous blood concentrations as a result of infusion dosing.

Usage

```
calc_analytic_css_1comp(
  chem.name = NULL,
  chem.cas = NULL,
  dtxsid = NULL,
  parameters = NULL,
  hourly.dose = 1/24,
  concentration = "plasma",
  suppress.messages = FALSE,
  recalc.blood2plasma = FALSE,
  tissue = NULL,
  restrictive.clearance = TRUE,
  bioactive.free.invivo = FALSE,
  ...
)
```

Arguments

chem.name	Either the chemical name, CAS number, or the parameters must be specified.
chem.cas	Either the chemical name, CAS number, or the parameters must be specified.

dtxsid	EPA's 'DSSTox Structure ID (https://comptox.epa.gov/dashboard) the chemical must be identified by either CAS, name, or DTXSIDs
parameters	Chemical parameters from parameterize_pbt (for model = 'pbt'), parameterize_3comp (for model = '3compartment'), parameterize_1comp (for model = '1compartment') or parameterize_steadystate (for model = '3compartmentss'), overrides chem.name and chem.cas.
hourly.dose	Hourly dose rate mg/kg BW/h.
concentration	Desired concentration type, 'blood' or default 'plasma'.
suppress.messages	Whether or not the output message is suppressed.
recalc.blood2plasma	Recalculates the ratio of the amount of chemical in the blood to plasma using the input parameters. Use this if you have altered hematocrit, Funbound.plasma, or Krbc2pu.
tissue	Desired tissue concentration (defaults to whole body concentration.)
restrictive.clearance	If TRUE (default), then only the fraction of chemical not bound to protein is available for metabolism in the liver. If FALSE, then all chemical in the liver is metabolized (faster metabolism due to rapid off-binding).
bioactive.free.invivo	If FALSE (default), then the total concentration is treated as bioactive in vivo. If TRUE, the the unbound (free) plasma concentration is treated as bioactive in vivo. Only works with tissue = NULL in current implementation.
...	Additional parameters passed to parameterize function if parameters is NULL.

Value

Steady state plasma concentration in mg/L units

Author(s)

Robert Pearce and John Wambaugh

calc_analytic_css_3comp

Calculate the analytic steady state concentration for model 3comp

Description

This function calculates the analytic steady state plasma or venous blood concentrations as a result of infusion dosing.

Usage

```
calc_analytic_css_3comp(
  chem.name = NULL,
  chem.cas = NULL,
  dtxsid = NULL,
  parameters = NULL,
```

```

    hourly.dose = 1/24,
    concentration = "plasma",
    suppress.messages = FALSE,
    recalc.blood2plasma = FALSE,
    tissue = NULL,
    restrictive.clearance = TRUE,
    bioactive.free.invivo = FALSE,
    ...
)

```

Arguments

chem.name	Either the chemical name, CAS number, or the parameters must be specified.
chem.cas	Either the chemical name, CAS number, or the parameters must be specified.
dtxsid	EPA's 'DSSTox Structure ID' (https://comptox.epa.gov/dashboard) the chemical must be identified by either CAS, name, or DTXIDs
parameters	Chemical parameters from parameterize_pbt (for model = 'pbt'), parameterize_3comp (for model = '3compartment'), parameterize_1comp (for model = '1compartment') or parameterize_steadystate (for model = '3compartmentss'), overrides chem.name and chem.cas.
hourly.dose	Hourly dose rate mg/kg BW/h.
concentration	Desired concentration type, 'blood' or default 'plasma'.
suppress.messages	Whether or not the output message is suppressed.
recalc.blood2plasma	Recalculates the ratio of the amount of chemical in the blood to plasma using the input parameters. Use this if you have 'altered hematocrit, Funbound.plasma, or Krbc2pu.
tissue	Desired tissue concentration (defaults to whole body concentration.)
restrictive.clearance	If TRUE (default), then only the fraction of chemical not bound to protein is available for metabolism in the liver. If FALSE, then all chemical in the liver is metabolized (faster metabolism due to rapid off-binding).
bioactive.free.invivo	If FALSE (default), then the total concentration is treated as bioactive in vivo. If TRUE, the the unbound (free) plasma concentration is treated as bioactive in vivo. Only works with tissue = NULL in current implementation.
...	Additional parameters passed to parameterize function if parameters is NULL.

Value

Steady state plasma concentration in mg/L units

Author(s)

Robert Pearce and John Wambaugh

calc_analytic_css_3compss

Calculate the analytic steady state concentration for the three compartment steady-state model

Description

This function calculates the analytic steady state plasma or venous blood concentrations as a result of infusion dosing.

Usage

```
calc_analytic_css_3compss(
  chem.name = NULL,
  chem.cas = NULL,
  dtxsid = NULL,
  parameters = NULL,
  hourly.dose = 1/24,
  concentration = "plasma",
  suppress.messages = FALSE,
  recalc.blood2plasma = FALSE,
  tissue = NULL,
  restrictive.clearance = TRUE,
  bioactive.free.invivo = FALSE,
  ...
)
```

Arguments

chem.name	Either the chemical name, CAS number, or the parameters must be specified.
chem.cas	Either the chemical name, CAS number, or the parameters must be specified.
dtxsid	EPA's 'DSSTox Structure ID (https://comptox.epa.gov/dashboard) the chemical must be identified by either CAS, name, or DTXSIDs
parameters	Chemical parameters from parameterize_pbtk (for model = 'pbtk'), parameterize_3comp (for model = '3compartment'), parameterize_1comp(for model = '1compartment') or parameterize_steadystate (for model = '3compartmentss'), overrides chem.name and chem.cas.
hourly.dose	Hourly dose rate mg/kg BW/h.
concentration	Desired concentration type, 'blood' or default 'plasma'.
suppress.messages	Whether or not the output message is suppressed.
recalc.blood2plasma	Recalculates the ratio of the amount of chemical in the blood to plasma using the input parameters. Use this if you have 'altered hematocrit, Funbound.plasma, or Krbc2pu.
tissue	Desired tissue concentration (defaults to whole body concentration.)
restrictive.clearance	If TRUE (default), then only the fraction of chemical not bound to protein is available for metabolism in the liver. If FALSE, then all chemical in the liver is metabolized (faster metabolism due to rapid off-binding).

bioactive.free.invivo

If FALSE (default), then the total concentration is treated as bioactive in vivo. If TRUE, the the unbound (free) plasma concentration is treated as bioactive in vivo. Only works with tissue = NULL in current implementation.

... Additional parameters passed to parameterize function if parameters is NULL.

Value

Steady state plasma concentration in mg/L units

Author(s)

Robert Pearce and John Wambaugh

calc_analytic_css_pbt

Calculate the analytic steady state plasma concentration for model pbt.

Description

This function calculates the analytic steady state plasma or venous blood concentrations as a result of infusion dosing.

Usage

```
calc_analytic_css_pbt(
  chem.name = NULL,
  chem.cas = NULL,
  dtxsid = NULL,
  parameters = NULL,
  hourly.dose = 1/24,
  concentration = "plasma",
  suppress.messages = FALSE,
  recalc.blood2plasma = FALSE,
  tissue = NULL,
  restrictive.clearance = TRUE,
  bioactive.free.invivo = FALSE,
  ...
)
```

Arguments

chem.name	Either the chemical name, CAS number, or the parameters must be specified.
chem.cas	Either the chemical name, CAS number, or the parameters must be specified.
dtxsid	EPA's 'DSSTox Structure ID (https://comptox.epa.gov/dashboard) the chemical must be identified by either CAS, name, or DTXSIDs
parameters	Chemical parameters from parameterize_pbt (for model = 'pbt'), parameterize_3comp (for model = '3compartment'), parameterize_1comp(for model = '1compartment') or parameterize_steadystate (for model = '3compartmentss'), overrides chem.name and chem.cas.

hourly.dose	Hourly dose rate mg/kg BW/h.
concentration	Desired concentration type, 'blood', 'tissue', or default 'plasma'.
suppress.messages	Whether or not the output message is suppressed.
recalc.blood2plasma	Recalculates the ratio of the amount of chemical in the blood to plasma using the input parameters. Use this if you have 'altered hematocrit, Funbound.plasma, or Krbc2pu.
tissue	Desired tissue concentration (defaults to whole body concentration.)
restrictive.clearance	If TRUE (default), then only the fraction of chemical not bound to protein is available for metabolism in the liver. If FALSE, then all chemical in the liver is metabolized (faster metabolism due to rapid off-binding).
bioactive.free.invivo	If FALSE (default), then the total concentration is treated as bioactive in vivo. If TRUE, the the unbound (free) plasma concentration is treated as bioactive in vivo. Only works with tissue = NULL in current implementation.
...	Additional parameters passed to parameterize function if parameters is NULL.

Value

Steady state plasma concentration in mg/L units

Author(s)

Robert Pearce and John Wambaugh

calc_css

Find the steady state concentration and the day it is reached.

Description

This function finds the day a chemical comes within the specified range of the analytical steady state venous blood or plasma concentration(from calc_analytic_css) for the multiple compartment, three compartment, and one compartment models, the fraction of the true steady state value reached on that day, the maximum concentration, and the average concentration at the end of the simulation.

Usage

```
calc_css(
  chem.name = NULL,
  chem.cas = NULL,
  dtxsid = NULL,
  parameters = NULL,
  species = "Human",
  f = 0.01,
  daily.dose = 1,
  doses.per.day = 3,
  days = 21,
  output.units = "uM",
```

```

    suppress.messages = FALSE,
    tissue = NULL,
    model = "pbtk",
    default.to.human = FALSE,
    f.change = 1e-05,
    adjusted.funbound.plasma = TRUE,
    regression = TRUE,
    well.stirred.correction = TRUE,
    restrictive.clearance = TRUE,
    dosing = NULL,
    ...
)

```

Arguments

chem.name	Either the chemical name, CAS number, or parameters must be specified.
chem.cas	Either the chemical name, CAS number, or parameters must be specified.
dtxsid	EPA's DSSTox Structure ID (https://comptox.epa.gov/dashboard) the chemical must be identified by either CAS, name, or DTXSIDs
parameters	Chemical parameters from parameterize_pbtk function, overrides chem.name and chem.cas.
species	Species desired (either "Rat", "Rabbit", "Dog", "Mouse", or default "Human").
f	Fractional distance from the final steady state concentration that the average concentration must come within to be considered at steady state.
daily.dose	Total daily dose, mg/kg BW.
doses.per.day	Number of doses per day.
days	Initial number of days to run simulation that is multiplied on each iteration.
output.units	Units for returned concentrations, defaults to uM (specify units = "uM") but can also be mg/L.
suppress.messages	Whether or not to suppress messages.
tissue	Desired tissue concentration (default value is NULL, will depend on model – see steady.state.compartment in model.info file for further details.)
model	Model used in calculation, 'pbtk' for the multiple compartment model, '3compartment' for the three compartment model, and '1compartment' for the one compartment model.
default.to.human	Substitutes missing animal values with human values if true (hepatic intrinsic clearance or fraction of unbound plasma).
f.change	Fractional change of daily steady state concentration reached to stop calculating.
adjusted.funbound.plasma	Uses adjusted funbound.plasma when set to TRUE along with partition coefficients calculated with this value.
regression	Whether or not to use the regressions in calculating partition coefficients.
well.stirred.correction	Uses correction in calculation of hepatic clearance for well-stirred model if TRUE for model 1compartment elimination rate. This assumes clearance relative to amount unbound in whole blood instead of plasma, but converted to use with plasma concentration.

restrictive.clearance	Protein binding not taken into account (set to 1) in liver clearance if FALSE.
dosing	The dosing object for more complicated scenarios. Defaults to repeated daily.dose spread out over doses.per.day
...	Additional arguments passed to model solver (default of solve_pbtck).

Value

frac	Ratio of the mean concentration on the day steady state is reached (baed on doses.per.day) to the analytical C _{ss} (based on infusion dosing).
max	The maximum concentration of the simulation.
avg	The average concentration on the final day of the simulation.
the.day	The day the average concentration comes within 100 * p percent of the true steady state concentration.

Author(s)

Robert Pearce, John Wambaugh

Examples

```
calc_css(chem.name='Bisphenol-A',doses.per.day=5,f=.001,output.units='mg/L')

parms <- parameterize_3comp(chem.name='Bisphenol-A')
parms$Funbound.plasma <- .07
calc_css(chem.name='Bisphenol-A',parameters=parms,model='3compartment')

out <- solve_pbtck(chem.name = "Bisphenol A",
  days = 50,
  daily.dose=1,
  doses.per.day = 3)
plot.data <- as.data.frame(out)

css <- calc_analytic_css(chem.name = "Bisphenol A")
library("ggplot2")
c.vs.t <- ggplot(plot.data,aes(time, Cplasma)) + geom_line() +
  geom_hline(yintercept = css) + ylab("Plasma Concentration (uM)") +
  xlab("Day") + theme(axis.text = element_text(size = 16), axis.title =
  element_text(size = 16), plot.title = element_text(size = 17)) +
  ggtitle("Bisphenol A")

print(c.vs.t)
```

calc_elimination_rate *Calculate the elimination rate for a one compartment model*

Description

This function calculates an elimination rate from the three compartment steady state model where elimination is entirely due to metabolism by the liver and glomerular filtration in the kidneys.

Usage

```
calc_elimination_rate(
  chem.cas = NULL,
  chem.name = NULL,
  dtxsid = NULL,
  parameters = NULL,
  species = "Human",
  suppress.messages = FALSE,
  default.to.human = FALSE,
  restrictive.clearance = TRUE,
  adjusted.Funbound.plasma = TRUE,
  adjusted.Clint = TRUE,
  regression = TRUE,
  well.stirred.correction = TRUE,
  clint.pvalue.threshold = 0.05,
  minimum.Funbound.plasma = 1e-04
)
```

Arguments

chem.cas	Either the cas number or the chemical name must be specified.
chem.name	Either the chemical name or the cas number must be specified.
dtxsid	EPA's 'DSSTox Structure ID (https://comptox.epa.gov/dashboard) the chemical must be identified by either CAS, name, or DTXSIDs
parameters	Chemical parameters from parameterize_steadystate or 1compartment function, overrides chem.name and chem.cas.
species	Species desired (either "Rat", "Rabbit", "Dog", "Mouse", or default "Human").
suppress.messages	Whether or not the output message is suppressed.
default.to.human	Substitutes missing animal values with human values if true.
restrictive.clearance	In calculating elimination rate, protein binding is not taken into account (set to 1) in liver clearance if FALSE.
adjusted.Funbound.plasma	Uses adjusted Funbound.plasma when set to TRUE along with partition coefficients calculated with this value.
adjusted.Clint	Uses Kilford et al. (2008) hepatocyte incubation binding adjustment for Clint when set to TRUE (Default).
regression	Whether or not to use the regressions in calculating partition coefficients.
well.stirred.correction	Uses correction in calculation of hepatic clearance for -stirred model if TRUE. This assumes clearance relative to amount unbound in whole blood instead of plasma, but converted to use with plasma concentration.
clint.pvalue.threshold	Hepatic clearance for chemicals where the in vitro clearance assay result has a p-values greater than the threshold are set to zero.
minimum.Funbound.plasma	Monte Carlo draws less than this value are set equal to this value (default is 0.0001 – half the lowest measured Fup in our dataset).

Details

Elimination rate calculated by dividing the total clearance (using the default -stirred hepatic model) by the volume of distribution. When species is specified as rabbit, dog, or mouse, the function uses the appropriate physiological data(volumes and flows) but substitutes human fraction unbound, partition coefficients, and intrinsic hepatic clearance.

Value

Elimination rate
Units of 1/h.

calc_fetal_phys

Calculate maternal-fetal physiological parameters

Description

This function uses the equations from Kapraun (2019) to calculate chemical- independent physiological parameters as a function of gestational age in weeks.

Usage

```
calc_fetal_phys(week = 12, ...)
```

Arguments

week	Gestational week
...	Additional arguments to parameterize_fetal_pbt

Details

calc_half_life	<i>Calculates the half-life for a one compartment model.</i>
----------------	--

Description

This function calculates the half life from the three compartment steady state model where elimination is entirely due to metabolism by the liver and glomerular filtration in the kidneys.

Usage

```
calc_half_life(
  chem.cas = NULL,
  chem.name = NULL,
  dtxsid = NULL,
  parameters = NULL,
  species = "Human",
  suppress.messages = FALSE,
  default.to.human = FALSE,
```

```

restrictive.clearance = TRUE,
adjusted.Funbound.plasma = TRUE,
regression = TRUE,
well.stirred.correction = TRUE,
clint.pvalue.threshold = 0.05,
minimum.Funbound.plasma = 1e-04
)

```

Arguments

chem.cas	Either the cas number or the chemical name must be specified.
chem.name	Either the chemical name or the cas number must be specified.
dtxsid	EPA's 'DSSTox Structure ID (https://comptox.epa.gov/dashboard) the chemical must be identified by either CAS, name, or DTXSIDs
parameters	Chemical parameters from parameterize_steadystate or 1compartment function, overrides chem.name and chem.cas.
species	Species desired (either "Rat", "Rabbit", "Dog", "Mouse", or default "Human").
suppress.messages	Whether or not the output message is suppressed.
default.to.human	Substitutes missing animal values with human values if true.
restrictive.clearance	In calculating elimination rate, protein binding is not taken into account (set to 1) in liver clearance if FALSE.
adjusted.Funbound.plasma	Uses adjusted Funbound.plasma when set to TRUE along with partition coefficients calculated with this value.
regression	Whether or not to use the regressions in calculating partition coefficients.
well.stirred.correction	Uses correction in calculation of hepatic clearance for -stirred model if TRUE. This assumes clearance relative to amount unbound in whole blood instead of plasma, but converted to use with plasma concentration.
clint.pvalue.threshold	Hepatic clearance for chemicals where the in vitro clearance assay result has a p-values greater than the threshold are set to zero.
minimum.Funbound.plasma	Monte Carlo draws less than this value are set equal to this value (default is 0.0001 – half the lowest measured Fup in our dataset).

Details

Half life is calculated by dividing the natural-log of 2 by the elimination rate from the one compartment model.

Value

Half life Units of h.

Author(s)

Sarah E. Davidson

[calc_elimination_rate()] for the elimination rate calculation

Examples

```
calc_half_life(chem.name="Bisphenol A")
calc_half_life(chem.name="Bisphenol A", species="Rat")
calc_half_life(chem.cas="80-05-7")
```

calc_hepatic_clearance

Calculate the hepatic clearance (deprecated).

Description

This function is included for backward compatibility. It calls [calc_hep_clearance](#) which calculates the hepatic clearance in plasma for a well-stirred model or other type if specified. Based on Ito and Houston (2004)

Usage

```
calc_hepatic_clearance(
  chem.name = NULL,
  chem.cas = NULL,
  dtxsid = NULL,
  parameters = NULL,
  species = "Human",
  default.to.human = FALSE,
  hepatic.model = "well-stirred",
  suppress.messages = FALSE,
  well.stirred.correction = TRUE,
  restrictive.clearance = TRUE,
  adjusted.funbound.plasma = TRUE,
  ...
)
```

Arguments

chem.name	Either the chemical name, CAS number, or the parameters must be specified.
chem.cas	Either the chemical name, CAS number, or the parameters must be specified.
dtxsid	EPA's DSSTox Structure ID (https://comptox.epa.gov/dashboard) the chemical must be identified by either CAS, name, or DTXSIDs
parameters	Chemical parameters from parameterize_steadystate function, overrides chem.name and chem.cas.
species	Species desired (either "Rat", "Rabbit", "Dog", "Mouse", or default "Human").
default.to.human	Substitutes missing animal values with human values if true.
hepatic.model	Model used in calculating hepatic clearance, unscaled, parallel tube, dispersion, or default well-stirred.

suppress.messages
Whether or not to suppress the output message.

well.stirred.correction
Uses correction in calculation of hepatic clearance for well-stirred model if TRUE for hepatic.model well-stirred. This assumes clearance relative to amount unbound in whole blood instead of plasma, but converted to use with plasma concentration.

restrictive.clearance
Protein binding not taken into account (set to 1) in liver clearance if FALSE.

adjusted.funbound.plasma
Uses adjusted funbound.plasma when set to TRUE.

...
Additional parameters passed to parameterize_steadystate if parameters is NULL.

Value

Hepatic Clearance
Units of L/h/kg BW.

Author(s)

John Wambaugh and Robert Pearce

Ito, K., & Houston, J. B. (2004). "Comparison of the use of liver models for predicting drug clearance using in vitro kinetic data from hepatic microsomes and isolated hepatocytes." *Pharmaceutical Research*, 21(5), 785-792.

Examples

```
calc_hep_clearance(chem.name="Ibuprofen",hepatic.model='unscaled')
calc_hep_clearance(chem.name="Ibuprofen",well.stirred.correction=FALSE)
```

calc_hep_bioavailability

Calculate first pass metabolism

Description

For models that don't described first pass blood flow from the gut, need to calculate a hepatic bioavailability, that is, the fraction of chemical systemically available after metabolism during the first pass through the liver (Rowland, 1973 Equation 29, where k_{21} is blood flow through the liver and k_{23} is clearance from the liver in Figure 1).

Usage

```
calc_hep_bioavailability(  
  chem.cas = NULL,  
  chem.name = NULL,  
  dtxsid = NULL,  
  parameters = NULL,  
  restrictive.clearance = TRUE,  
  flow.34 = TRUE  
)
```

Arguments

chem.cas	Chemical Abstract Services Registry Number (CAS-RN) – if parameters is not specified then the chemical must be identified by either CAS, name, or DTXISD
chem.name	Chemical name (spaces and capitalization ignored) – if parameters is not specified then the chemical must be identified by either CAS, name, or DTXISD
dtxsid	EPA's 'DSSTox Structure ID (https://comptox.epa.gov/dashboard) – if parameters is not specified then the chemical must be identified by either CAS, name, or DTXSIDs
parameters	Parameters from the appropriate parameterization function for the model indicated by argument model
restrictive.clearance	Protein binding not taken into account (set to 1) in liver clearance if FALSE.
flow.34	A logical constraint

Value

A data.table whose columns are the parameters of the HHTK model specified in model1.

calc_hep_clearance	<i>Calculate the hepatic clearance.</i>
--------------------	---

Description

This function calculates the hepatic clearance in plasma for using the Houston (2004) are also available. In vitro measured hepatic clearance is corrected for the free fraction in the assay using the model of Kilford et al. (2008).

Usage

```
calc_hep_clearance(
  chem.name = NULL,
  chem.cas = NULL,
  dtxsid = NULL,
  parameters = NULL,
  species = "Human",
  default.to.human = FALSE,
  hepatic.model = "well-stirred",
  suppress.messages = FALSE,
  well.stirred.correction = TRUE,
  restrictive.clearance = TRUE,
  adjusted.Funbound.plasma = TRUE,
  ...
)
```

Arguments

chem.name	Either the chemical name, CAS number, or the parameters must be specified.
chem.cas	Either the chemical name, CAS number, or the parameters must be specified.
dtxsid	EPA's DSSTox Structure ID (https://comptox.epa.gov/dashboard) the chemical must be identified by either CAS, name, or DTXSIDs
parameters	Chemical parameters from parameterize_steadystate function, overrides chem.name and chem.cas.
species	Species desired (either "Rat", "Rabbit", "Dog", "Mouse", or default "Human").
default.to.human	Substitutes missing animal values with human values if true.
hepatic.model	Model used in calculating hepatic clearance, unscaled, parallel tube, dispersion, or default well-stirred.
suppress.messages	Whether or not to suppress the output message.
well.stirred.correction	Uses correction in calculation of hepatic clearance for well-stirred model if TRUE for hepatic.model well-stirred. This assumes clearance relative to amount unbound in whole blood instead of plasma, but converted to use with plasma concentration.
restrictive.clearance	Protein binding not taken into account (set to 1) in liver clearance if FALSE.
adjusted.Funbound.plasma	Uses adjusted Funbound.plasma when set to TRUE.
...	Additional parameters passed to parameterize_steadystate if parameters is NULL.

Value

Hepatic Clearance
Units of L/h/kg BW.

Examples

```
calc_hep_clearance(chem.name="Ibuprofen",hepatic.model='unscaled')
calc_hep_clearance(chem.name="Ibuprofen",well.stirred.correction=FALSE)
```

calc_hep_fu

Calculate the free chemical in the hepatic clearance assay

Description

Method from Kilford et al. (2008) for fraction of unbound chemical in the hepatocyte intrinsic clearance assay

Usage

```
calc_hep_fu(
  chem.cas = NULL,
  chem.name = NULL,
  dtxsid = NULL,
  parameters = NULL,
  Vr = 0.005,
  pH = 7.4
)
```

Arguments

chem.cas	Chemical Abstract Services Registry Number (CAS-RN) – if parameters is not specified then the chemical must be identified by either CAS, name, or DTXISD
chem.name	Chemical name (spaces and capitalization ignored) – if parameters is not specified then the chemical must be identified by either CAS, name, or DTXISD
dtxsid	EPA's 'DSSTox Structure ID (https://comptox.epa.gov/dashboard) – if parameters is not specified then the chemical must be identified by either CAS, name, or DTXSIDs
parameters	Parameters from the appropriate parameterization function for the model indicated by argument model
Vr	Ratio of cell volume to incubation volume. Default is taken from
pH	pH of the incubation medium.

Value

A numeric fraction between zero and one

calc_ionization

Calculate the ionization.

Description

This function calculates the ionization of a compound at a given pH. The pKa's are either entered as parameters or taken from a specific compound in the package.

Usage

```
calc_ionization(  
  chem.cas = NULL,  
  chem.name = NULL,  
  dtxsid = NULL,  
  parameters = NULL,  
  pH = NULL,  
  pKa_Donor = NULL,  
  pKa_Accept = NULL  
)
```

Arguments

chem.cas	Either the chemical name or the CAS number must be specified.
chem.name	Either the chemical name or the CAS number must be specified.
dtxsid	EPA's 'DSSTox Structure ID (https://comptox.epa.gov/dashboard) the chemical must be identified by either CAS, name, or DTXSIDs
parameters	Chemical parameters from a parameterize_MODEL function, overrides chem.name and chem.cas.
pH	pH where ionization is evaluated.
pKa_Donor	Compound H dissociation equilibrium constant(s). Overwrites chem.name and chem.cas.
pKa_Accept	Compound H association equilibrium constant(s). Overwrites chem.name and chem.cas.

Details

The arguments pKa_Donor and pKa_Accept may be single numbers, characters, or vectors. We support characters because there are many instances with multiple predicted values and all those values can be included by concatenating with commas (for example, pKa_Donor = "8.1,8.6". Finally, pKa_Donor and pKa_Accept may be vectors of characters representing different chemicals or instances of chemical parameters to allow for uncertainty analysis.

The fractions are calculated by determining the coefficients for each species and dividing the particular species by the sum of all three. The positive, negative and zwitterionic/neutral coefficients are given by:

$$zwitter/neutral = 1$$

$$for(iin1 : pkaboveneutral)negative = negative + 10^{i * pH - pKa1 - \dots - pKai}$$

$$for(iin1 : pkbelowneutral)positive = positive + 10^{pKa1 + \dots + pKai - i * pH}$$

where i begins at 1 and ends at the number of points above(for negative) or below(for positive) the neutral/zwitterionic range. The neutral/zwitterionic range is either the pH range between 2 pKa's where the number of acceptors above is equal to the number of donors below, everything above the pKa acceptors if there are no donors, or everything below the pKa donors if there are no acceptors. Each of the terms in the sums represent a different ionization.

Value

```
fraction_neutral
      fraction of compound neutral
fraction_charged
      fraction of compound charged
fraction_negative
      fraction of compound negative
fraction_positive
      fraction of compound positive
fraction_zwitter
      fraction of compound zwitterionic
```

Author(s)

Robert Pearce and John Wambaugh

Strope, Cory L., et al. "High-throughput in-silico prediction of ionization equilibria for pharmacokinetic modeling." *Science of The Total Environment* 615 (2018): 150-160.

Examples

```
# Donor pKa's 9.78,10.39 -- Should be almost all neutral at plasma pH:
out <- calc_ionization(chem.name='bisphenola',pH=7.4)
print(out)
out[["fraction_neutral"]] == max(unlist(out))

# Donor pKa's 9.78,10.39 -- Should be almost all negative (anion) at higher pH:
out <- calc_ionization(chem.name='bisphenola',pH=11)
```

```

print(out)
out[["fraction_negative"]] == max(unlist(out))

# Fictious compound, should be almost all all negative (anion):
out <- calc_ionization(pKa_Donor=8,pKa_Accept="1,4",pH=9)
print(out)
out[["fraction_negative"]] > 0.9

# Donor pKa 6.54 -- Should be mostly negative (anion):
out <- calc_ionization(chem.name='Acephate',pH=7)
print(out)
out[["fraction_negative"]] == max(unlist(out))

#Acceptor pKa's "9.04,6.04" -- Should be almost all positive (cation) at plasma pH:
out <- calc_ionization(chem.cas="145742-28-5",pH=7.4)
print(out)
out[["fraction_positive"]] == max(unlist(out))

#Fictious Zwitteron:
out <- calc_ionization(pKa_Donor=6,pKa_Accept="8",pH=7.4)
print(out)
out[["fraction_zwitter"]] == max(unlist(out))

```

calc_krbc2pu

Back-calculates the Red Blood Cell to Unbound Plasma Partition Coefficient

Description

Given an observed ratio of chemical concentration in blood to plasma, this function calculates a Red Blood Cell to unbound plasma (K_{rbc2pu}) partition coefficient that would be consistent with that observation.

Usage

```

calc_krbc2pu(
  Rb2p,
  Funbound.plasma,
  hematocrit = NULL,
  default.to.human = FALSE,
  species = "Human",
  suppress.messages = TRUE
)

```

Arguments

Rb2p	The chemical blood:plasma concentration ratio
Funbound.plasma	The free fraction of chemical in the presence of plasma protein R _{blood2plasma} .
hematocrit	Overwrites default hematocrit value in calculating R _{blood2plasma} .
default.to.human	Substitutes missing animal values with human values if true.

species Species desired (either "Rat", "Rabbit", "Dog", "Mouse", or default "Human").
suppress.messages Determine whether to display certain usage feedback.

Value

The red blood cell to unbound chemical in plasma partition coefficient.

calc_maternal_bw	<i>Calculate maternal body weight</i>
------------------	---------------------------------------

Description

This function initializes the parameters needed in the functions solve_fetal_pbt by calling solve_pbt and adding additional parameters.

Usage

```
calc_maternal_bw(week = 12)
```

Arguments

week Gestational week

Details

```
BW <- params$pre_pregnant_BW + params$BW_cubic_theta1 * tw + params$BW_cubic_theta2  
* tw^2 + params$BW_cubic_theta3 * tw^3
```

Value

BW Maternal Body Weight, kg.

calc_mc_css

Distribution of chemical steady state concentration with uncertainty and variability

Description

For a given chemical and fixed dose rate this function determines a distribution of steady-state concentrations reflecting measurement uncertainty and population variability. Uncertainty and variability are simulated via the Monte Carlo method – many sets of model parameters are drawn according to probability distributions described in Ring et al. (2017) ([doi:10.1016/j.envint.2017.06.004](https://doi.org/10.1016/j.envint.2017.06.004)) for human variability and Wambaugh et al. (2019) ([doi:10.1093/toxsci/kfz205](https://doi.org/10.1093/toxsci/kfz205)) for measurement uncertainty. Monte Carlo samples are generated by the function `create_mc_samples`. To allow rapid application of the Monte Carlo method we make use of analytical solutions for the steady-state concentration for a particular model via a given route (when available) as opposed to solving the model numerically (that is, using differential equations). For each sample of the Monte Carlo method (as specified by argument `samples`) the parameters for the analytical solution are varied. An ensemble of steady-state predictions are produced, though by default only the quantiles specified by argument `which.quantile` are provided. If the full set of predicted values are desired use set the argument `return.samples` to TRUE.

Usage

```
calc_mc_css(
  chem.cas = NULL,
  chem.name = NULL,
  dtxsid = NULL,
  parameters = NULL,
  samples = 1000,
  which.quantile = 0.95,
  species = "Human",
  suppress.messages = FALSE,
  model = "3compartmentss",
  httkpop = TRUE,
  invitrouv = TRUE,
  calcrb2p = TRUE,
  censored.params = list(),
  vary.params = list(),
  return.samples = FALSE,
  tissue = NULL,
  concentration = "plasma",
  output.units = "mg/L",
  invitro.mc.arg.list = list(adjusted.Funbound.plasma = TRUE, poormetab = TRUE,
    fup.censored.dist = FALSE, fup.lod = 0.01, fup.meas.cv = 0.4, clint.meas.cv = 0.3,
    fup.pop.cv = 0.3, clint.pop.cv = 0.3),
  httkpop.generate.arg.list = list(method = "direct resampling", gendernum = NULL,
    agelim_years = NULL, agelim_months = NULL, weight_category = c("Underweight",
    "Normal", "Overweight", "Obese"), gfr_category = c("Normal", "Kidney Disease",
    "Kidney Failure"), reths = c("Mexican American", "Other Hispanic",
    "Non-Hispanic White", "Non-Hispanic Black", "Other")),
  convert.httkpop.arg.list = list(),
  parameterize.arg.list = list(default.to.human = FALSE, clint.pvalue.threshold = 0.05,
```

```

    restrictive.clearance = TRUE, regression = TRUE),
  calc.analytic.css.arg.list = list(),
  parameterize.args = list(default.to.human = FALSE, adjusted.Funbound.plasma = TRUE,
    regression = TRUE, minimum.Funbound.plasma = 1e-04)
)

```

Arguments

chem.cas	Chemical Abstract Services Registry Number (CAS-RN) – if parameters is not specified then the chemical must be identified by either CAS, name, or DTXISD
chem.name	Chemical name (spaces and capitalization ignored) – if parameters is not specified then the chemical must be identified by either CAS, name, or DTXISD
dtxsid	EPA's DSSTox Structure ID (https://comptox.epa.gov/dashboard) – if parameters is not specified then the chemical must be identified by either CAS, name, or DTXISDs
parameters	Parameters from the appropriate parameterization function for the model indicated by argument model
samples	Number of samples generated in calculating quantiles.
which.quantile	Which quantile from Monte Carlo simulation is requested. Can be a vector.
species	Species desired (either "Rat", "Rabbit", "Dog", "Mouse", or default "Human"). Species must be set to "Human" to run httkpop model.
suppress.messages	Whether or not to suppress output message.
model	Model used in calculation, 'gas_pbt' for the gas pbt model, 'pbt' for the multiple compartment model, '3compartment' for the three compartment model, '3compartmentss' for the three compartment steady state model, and '1compartment' for one compartment model. This only applies when httkpop=TRUE and species="Human", otherwise '3compartmentss' is used.
httkpop	Whether or not to use population generator and sampler from httkpop. This is overwrites censored.params and vary.params and is only for human physiology. Species must also be set to 'Human'.
invitrouv	Logical to indicate whether to include in vitro parameters in uncertainty and variability analysis
calcrb2p	Logical determining whether or not to recalculate the chemical ratio of blood to plasma
censored.params	The parameters listed in censored.params are sampled from a normal distribution that is censored for values less than the limit of detection (specified separately for each parameter). This argument should be a list of sublists. Each sublist is named for a parameter in "parameters" and contains two elements: "CV" (coefficient of variation) and "LOD" (limit of detection, below which parameter values are censored. New values are sampled with mean equal to the value in "parameters" and standard deviation equal to the mean times the CV. Censored values are sampled on a uniform distribution between 0 and the limit of detection. Not used with httkpop model.
vary.params	The parameters listed in vary.params are sampled from a normal distribution that is truncated at zero. This argument should be a list of coefficients of variation (CV) for the normal distribution. Each entry in the list is named for a parameter

	in "parameters". New values are sampled with mean equal to the value in "parameters" and standard deviation equal to the mean times the CV. Not used with httkpop model.
return.samples	Whether or not to return the vector containing the samples from the simulation instead of the selected quantile.
tissue	Desired steady state tissue concentration. Default is of NULL typically gives whole body plasma concentration.
concentration	Desired concentration type: 'blood', 'tissue', or default 'plasma'. In the case that the concentration is for plasma, selecting "blood" will use the blood:plasma ratio to estimate blood concentration. In the case that the argument 'tissue' specifies a particular tissue of the body, concentration defaults to 'tissue' – that is, the concentration in the If cocentration is set to 'blood' or 'plasma' and 'tissue' specifies a specific tissue then the value returned is for the plasma or blood in that specific tissue.
output.units	Plasma concentration units, either uM or default mg/L.
invitro.mc.arg.list	List of additional parameters passed to invitro_mc
httkpop.generate.arg.list	Additional parameters passed to httkpop_generate .
convert.httkpop.arg.list	Additional parameters passed to the convert_httkpop_* function for the model.
parameterize.arg.list	Additional parameters passed to the parameterize_* function for the model.
calc.analytic.css.arg.list	Additional parameters passed to calc_analytic_css .
parameterize.args	A list of arguments to be passed to the model parameterization function (that is, parameterize_MODEL) corresponding to argument "model". (Defaults to NULL.)

Details

The chemical-specific steady-state concentration for a dose rate of 1 mg/kg body weight/day can be used for *in vitro-in vivo* extrapolation (IVIVE) of a bioactive *in vitro* concentration by dividing the *in vitro* concentration by the steady-state concentration to predict a dose rate (mg/kg/day) that would produce that concentration in plasma. Using quantiles of the distribution (such as the upper 95th percentile) allow incorporation of uncertainty and variability into IVIVE.

Reverse Dosimetry Toxicodynamic IVIVE

$$AED_{C_{ss,95}} = \frac{[X]}{C_{ss,95}}$$

altalt

Figure from Breen et al. (2021) ([doi:10.1080/17425255.2021.1935867](https://doi.org/10.1080/17425255.2021.1935867)) shows reverse dosimetry toxicodynamic IVIVE. Equivalent external dose is determined by solving the TK model in reverse by deriving the external dose (that is, TK model input) that produces a specified internal concentration (that is, TK model output). Reverse dosimetry and IVIVE using HHTK relies on the linearity of the models. We calculate a scaling factor to relate *in vitro* concentrations (uM) to administered equivalent doses (AED). The scaling factor is the inverse of the steady state plasma concentration (C_{ss}) predicted for a 1 mg/kg/day exposure dose rate. We use Monte Carlo to simulate variability and propagate uncertainty; for example, to calculate an upper 95th percentile C_{ss,95} for individuals who get higher plasma concentrations from the same exposure.

The Monte Carlo methods used here were recently updated and described by Breen et al. (submitted).

httk-pop is used only for humans. For non-human species biological variability is simulated by drawing parameters from uncorellated log-normal distributions.

Chemical-specific httk data are available primarily for human and for a few hundred chemicals in rat. All in silico predictions are for human. Thus, when species is specified as rabbit, dog, or mouse, the user can choose to set the argument default.to.human to TRUE so that this function uses the appropriate physiological data (volumes and flows) but substitutes human fraction unbound, partition coefficients, and intrinsic hepatic clearance.

If the argument tissue is used, the steady-state concentration in that tissue, if available, is provided. If that tissue is included in the model used (specified by arguement model1) then the actual tissue concentration is provided. Otherwise, the tissue-specific partition coefficient is used to estimate the concentration from the plasma.

The six sets of plausible IVIVE assumptions identified by Honda et al. (2019) ([doi:10.1371/journal.pone.0217564](https://doi.org/10.1371/journal.pone.0217564)) are:

	<i>in vivo</i> Conc.	Metabolic Clearance	Bioactive Chemical Conc.	TK Statistic Used*
Honda1	Veinous (Plasma)	Restrictive	Free	Mean Conc.
Honda2	Veinous	Restrictive	Free	Max Conc.

Honda3	Veinous	Non-restrictive	Total	Mean Conc.
Honda4	Veinous	Non-restrictive	Total	Max Conc.
Honda5	Target Tissue	Non-restrictive	Total	Mean Conc.
Honda6	Target Tissue	Non-restrictive	Total	Max Conc.

*Assumption is currently ignored because analytical steady-state solutions are currently used by this function.

Value

Quantiles (specified by which.quantile) of the distribution of plasma steady-state concentration (C_{ss}) from the Monte Carlo simulation

```

Description

This function converts a chemical plasma concentration to an oral administered equivalent dose (AED) using a concentration obtained from `calc_mc_css`. This function uses reverse dosimetry-based *in vitro-in vivo* extrapolation (IVIVE) for high throughput risk screening. The user can input the chemical and *in vitro* bioactive concentration, select the TK model, and then automatically predict the *in vivo* AED which would produce a body concentration equal to the *in vitro* bioactive concentration. This function relies on the Monte Carlo method (via function `create_mc_samples` to simulate both uncertainty and variability so that the result is a distribution of equivalent doses, from which we provide specific quantiles (specified by `which.quantile`), though the full set of predictions can be obtained by setting `return.samples` to `TRUE`.

Usage

```
calc_mc_oral_equiv(
  conc,
  chem.name = NULL,
  chem.cas = NULL,
  dtxsid = NULL,
  which.quantile = 0.95,
  species = "Human",
  input.units = "uM",
  output.units = "mgpkgpday",
  suppress.messages = FALSE,
  return.samples = FALSE,
  restrictive.clearance = TRUE,
  bioactive.free.invivo = FALSE,
  tissue = NULL,
  concentration = "plasma",
  IVIVE = NULL,
  model = "3compartmentss",
  ...
)
```

Arguments

<code>conc</code>	Bioactive in vitro concentration in units of uM.
<code>chem.name</code>	Either the chemical name or the CAS number must be specified.
<code>chem.cas</code>	Either the CAS number or the chemical name must be specified.
<code>dtxsid</code>	EPA's 'DSSTox Structure ID (https://comptox.epa.gov/dashboard) the chemical must be identified by either CAS, name, or DTXSIDs
<code>which.quantile</code>	Which quantile from Monte Carlo steady-state simulation (<code>calc_mc_css</code>) is requested. Can be a vector. Note that 95th concentration quantile is the same population as the 5th dose quantile.
<code>species</code>	Species desired (either "Rat", "Rabbit", "Dog", "Mouse", or default "Human").
<code>input.units</code>	Units of given concentration, default of uM but can also be mg/L.
<code>output.units</code>	Units of dose, default of 'mgpkgpday' for mg/kg BW/ day or 'umolpkgpday' for umol/ kg BW/ day.
<code>suppress.messages</code>	Suppress text messages.

return.samples	Whether or not to return the vector containing the samples from the simulation instead of the selected quantile.
restrictive.clearance	Protein binding not taken into account (set to 1) in liver clearance if FALSE.
bioactive.free.invivo	If FALSE (default), then the total concentration is treated as bioactive in vivo. If TRUE, the the unbound (free) plasma concentration is treated as bioactive in vivo. Only works with tissue = NULL in current implementation.
tissue	Desired steady state tissue concentration. Default is of NULL typically gives whole body plasma concentration.
concentration	Desired concentration type: 'blood','tissue', or default 'plasma'. In the case that the concentration is for plasma, selecting "blood" will use the blood:plasma ratio to estimate blood concentration. In the case that the argument 'tissue' specifies a particular tissue of the body, concentration defaults to 'tissue' – that is, the concentration in the If cocentration is set to 'blood' or 'plasma' and 'tissue' specifies a specific tissue then the value returned is for the plasma or blood in that specific tissue.
IVIVE	Honda et al. (2019) identified six plausible sets of assumptions for <i>in vitro-in vivo</i> extrapolation (IVIVE) assumptions. Argument may be set to "Honda1" through "Honda6". If used, this function overwrites the tissue, restrictive.clearance, and plasma.binding arguments. See Details below for more information.
model	Model used in calculation,'gas_pbt' for the gas pbt model, 'pbt' for the multiple compartment model, '3compartment' for the three compartment model, '3compartmentss' for the three compartment steady state model, and '1compartment' for one compartment model. This only applies when httkpop=TRUE and species="Human", otherwise '3compartmentss' is used.
...	Additional parameters passed to calc_mc_css for httkpop and variance of parameters.

Details

The chemical-specific steady-state concentration for a dose rate of 1 mg/kg body weight/day can be used for in IVIVE of a bioactive *in vitro* concentration by dividing the *in vitro* concentration by the steady-state concentration to predict a dose rate (mg/kg/day) that would produce that concentration in plasma. Using quantiles of the distribution (such as the upper 95th percentile) allow incorporation of uncertainty and variability into IVIVE.

This approach relies on the linearity of the models to calculate a scaling factor to relate in vitro concentrations (uM) with AED. The scaling factor is the inverse of the steady-state plasma concentration (C_{ss}) predicted for a 1 mg/kg/day exposure dose rate where *in vitro* concentration [X] and C_{ss} must be in the same units. Note that it is typical for *in vitro* concentrations to be reported in units of uM and C_{ss} in units of mg/L, in which case one must be converted to the other.

Reverse Dosimetry Toxicodynamic IVIVE

$$AED_{C_{ss,95}} = \frac{[X]}{C_{ss,95}}$$

altalt

Figure from Breen et al. (2021) ([doi:10.1080/17425255.2021.1935867](https://doi.org/10.1080/17425255.2021.1935867)) shows reverse dosimetry toxicodynamic IVIVE. Equivalent external dose is determined by solving the TK model in reverse by deriving the external dose (that is, TK model input) that produces a specified internal concentration (that is, TK model output). Reverse dosimetry and IVIVE using HHTK relies on the linearity of the models. We calculate a scaling factor to relate *in vitro* concentrations (uM) to AEDs. The scaling factor is the inverse of the C_{ss} predicted for a 1 mg/kg/day exposure dose rate. We use Monte Carlo to simulate variability and propagate uncertainty; for example, to calculate an upper 95th percentile C_{ss,95} for individuals who get higher plasma concentrations from the same exposure.

The Monte Carlo methods used here were recently updated and described by Breen et al. (submitted).

All arguments after httkpop only apply if httkpop is set to TRUE and species to "Human".

When species is specified as rabbit, dog, or mouse, the function uses the appropriate physiological data(volumes and flows) but substitutes human fraction unbound, partition coefficients, and intrinsic hepatic clearance.

Tissue concentrations are calculated for the pbtk model with oral infusion dosing. All tissues other than gut, liver, and lung are the product of the steady state plasma concentration and the tissue to plasma partition coefficient.

The six sets of plausible IVIVE assumptions identified by Honda et al. (2019) ([doi:10.1371/journal.pone.0217564](https://doi.org/10.1371/journal.pone.0217564)) are:

	<i>in vivo</i> Conc.	Metabolic Clearance	Bioactive Chemical Conc.	TK Statistic Used*
Honda1	Veinous (Plasma)	Restrictive	Free	Mean Conc.
Honda2	Veinous	Restrictive	Free	Max Conc.
Honda3	Veinous	Non-restrictive	Total	Mean Conc.
Honda4	Veinous	Non-restrictive	Total	Max Conc.
Honda5	Target Tissue	Non-restrictive	Total	Mean Conc.
Honda6	Target Tissue	Non-restrictive	Total	Max Conc.

*Assumption is currently ignored because analytical steady-state solutions are currently used by this function.

Value

Equivalent dose in specified units, default of mg/kg BW/day.

Examples

```
# Basic in vitro - in vivo extrapolation with httk, convert 0.5 uM in vitro
# concentration of chemical Surinabant to mg/kg/day:
set.seed(1234)
0.5/calc_mc_css(chem.name="Surinabant",samples=10,output.units="uM")
# The significant digits should give the same answer as:
set.seed(1234)
calc_mc_oral_equiv(chem.name="Surinabant",conc=0.5,samples=10)
# Note that we use set.seed to get the same sequence of random numbers for
# the two different function calls (calc_mc_css and calc_mc_oral_equiv)

# The following example should result in an error since we do not
# estimate tissue partitioning with '3compartmentss'.
set.seed(1234)
try(calc_mc_oral_equiv(0.1,chem.cas="34256-82-1",which.quantile=c(0.05,0.5,0.95),
                      tissue='brain'))

set.seed(1234)
calc_mc_oral_equiv(0.1,chem.cas="34256-82-1",model='pbtk',
                  which.quantile=c(0.05,0.5,0.95),tissue='brain')
```

calc_mc_tk

*Conduct multiple TK simulations using Monte Carlo***Description**

This function finds the analytical steady state plasma concentration(from calc_analytic_css) using a monte carlo simulation (monte_carlo).

Usage

```
calc_mc_tk(
  chem.cas = NULL,
  chem.name = NULL,
  dtxsid = NULL,
  parameters = NULL,
  samples = 1000,
  which.quantile = 0.95,
  species = "Human",
  suppress.messages = FALSE,
  model = "pbtk",
  httkpop = TRUE,
  invitrouv = TRUE,
  calcrb2p = TRUE,
  censored.params = list(),
  vary.params = list(),
  return.samples = FALSE,
  tissue = NULL,
  output.units = "mg/L",
  solvemodel.arg.list = list(times = c(0, 0.25, 0.5, 0.75, 1, 1.5, 2, 2.5, 3, 4, 5)),
  invitro.mc.arg.list = list(adjusted.Funbound.plasma = TRUE, poormetab = TRUE,
    fup.censored.dist = FALSE, fup.lod = 0.01, fup.meas.cv = 0.4, clint.meas.cv = 0.3,
    fup.pop.cv = 0.3, clint.pop.cv = 0.3),
  httkpop.generate.arg.list = list(method = "direct resampling", gendernum = NULL,
    agelim_years = NULL, agelim_months = NULL, weight_category = c("Underweight",
    "Normal", "Overweight", "Obese"), gfr_category = c("Normal", "Kidney Disease",
    "Kidney Failure"), reths = c("Mexican American", "Other Hispanic",
    "Non-Hispanic White", "Non-Hispanic Black", "Other")),
  convert.httkpop.arg.list = list(),
  parameterize.arg.list = list(default.to.human = FALSE, clint.pvalue.threshold = 0.05,
    restrictive.clearance = TRUE, regression = TRUE),
  return.all.sims = FALSE
)
```

Arguments

chem.cas	Either the CAS number, parameters, or the chemical name must be specified.
chem.name	Either the chemical parameters, name, or the CAS number must be specified.
dtxsid	EPA's DSSTox Structure ID (https://comptox.epa.gov/dashboard) the chemical must be identified by either CAS, name, or DTXSIDs
parameters	Parameters from parameterize_steadystate. Not used with httkpop model.

<code>samples</code>	Number of samples generated in calculating quantiles.
<code>which.quantile</code>	Which quantile from Monte Carlo simulation is requested. Can be a vector.
<code>species</code>	Species desired (either "Rat", "Rabbit", "Dog", "Mouse", or default "Human"). Species must be set to "Human" to run httkpop model.
<code>suppress.messages</code>	Whether or not to suppress output message.
<code>model</code>	Model used in calculation: 'pbtk' for the multiple compartment model, '3compartment' for the three compartment model, '3compartmentss' for the three compartment steady state model, and '1compartment' for one compartment model. This only applies when httkpop=TRUE and species="Human", otherwise '3compartmentss' is used.
<code>httkpop</code>	Whether or not to use population generator and sampler from httkpop. This is overwrites censored.params and vary.params and is only for human physiology. Species must also be set to 'Human'.
<code>invitrouv</code>	Logical to indicate whether to include in vitro parameters in uncertainty and variability analysis
<code>calcrb2p</code>	Logical determining whether or not to recalculate the chemical ratio of blood to plasma
<code>censored.params</code>	The parameters listed in censored.params are sampled from a normal distribution that is censored for values less than the limit of detection (specified separately for each parameter). This argument should be a list of sub-lists. Each sublist is named for a parameter in "parameters" and contains two elements: "CV" (coefficient of variation) and "LOD" (limit of detection, below which parameter values are censored. New values are sampled with mean equal to the value in "parameters" and standard deviation equal to the mean times the CV. Censored values are sampled on a uniform distribution between 0 and the limit of detection. Not used with httkpop model.
<code>vary.params</code>	The parameters listed in vary.params are sampled from a normal distribution that is truncated at zero. This argument should be a list of coefficients of variation (CV) for the normal distribution. Each entry in the list is named for a parameter in "parameters". New values are sampled with mean equal to the value in "parameters" and standard deviation equal to the mean times the CV. Not used with httkpop model.
<code>return.samples</code>	Whether or not to return the vector containing the samples from the simulation instead of the selected quantile.
<code>tissue</code>	Desired steady state tissue concentration.
<code>output.units</code>	Plasma concentration units, either uM or default mg/L.
<code>solvemodel.arg.list</code>	Additional arguments ultimately passed to solve_model
<code>invitro.mc.arg.list</code>	List of additional parameters passed to invitro_mc
<code>httkpop.generate.arg.list</code>	Additional parameters passed to httkpop_generate .
<code>convert.httkpop.arg.list</code>	Additional parameters passed to the <code>convert_httkpop_*</code> function for the model.
<code>parameterize.arg.list</code>	Additional parameters passed to the <code>parameterize_*</code> function for the model.

return.all.sims

Logical indicating whether to return the results of all simulations, in addition to the default toxicokinetic statistics

Details

The Monte Carlo methods used here were recently updated and described by Breen et al. (submitted).

All arguments after httkpop only apply if httkpop is set to TRUE and species to "Human".

When species is specified as rabbit, dog, or mouse, the function uses the appropriate physiological data(volumes and flows) but substitutes human fraction unbound, partition coefficients, and intrinsic hepatic clearance.

Tissue concentrations are calculated for the pbtk model with oral infusion dosing. All tissues other than gut, liver, and lung are the product of the steady state plasma concentration and the tissue to plasma partition coefficient.

The six sets of plausible *in vitro-in vivo* extrapolation (IVIVE) assumptions identified by Honda et al. (2019) ([doi:10.1371/journal.pone.0217564](https://doi.org/10.1371/journal.pone.0217564)) are:

	<i>in vivo</i> Conc.	Metabolic Clearance	Bioactive Chemical Conc.	TK Statistic Used*
Honda1	Veinous (Plasma)	Restrictive	Free	Mean Conc.
Honda2	Veinous	Restrictive	Free	Max Conc.
Honda3	Veinous	Non-restrictive	Total	Mean Conc.
Honda4	Veinous	Non-restrictive	Total	Max Conc.
Honda5	Target Tissue	Non-restrictive	Total	Mean Conc.
Honda6	Target Tissue	Non-restrictive	Total	Max Conc.

*Assumption is currently ignored because analytical steady-state solutions are currently used by this function.

Value

If return.all.sims == FALSE (default) a list with:

means	The mean concentration for each model compartment as a function of time across the Monte Carlo simulation
sds	The standard deviation for each model compartment as a function of time across the Monte Carlo simulation

If return.all.sims == TRUE then a list is returned with:

stats	The list of means and sds from return.all.sims=FALSE
sims	The concentration vs. time results for each compartment for every (samples) set of parameters in the Monte Carlo simulation

Examples

```

NSAMP <- 50
chemname="Abamectin"
times<- c(0,0.25,0.5,0.75,1,1.5,2,2.5,3,4,5)
age.ranges <- seq(6,80,by=10)
forward <- NULL
for (age.lower in age.ranges)
{
  label <- paste("Ages ",age.lower,"-",age.lower+4,sep="")
  set.seed(1234)
  forward[[label]] <- calc_mc_tk(
    chem.name=chemname,
    samples=NSAMP,
    httkpop.generate.arg.list=list(
      method="d",
      agelim_years = c(age.lower, age.lower+9)),
    solvemodell.arg.list = list(
      times=times))
}

```

calc_rblood2plasma	<i>Calculate the constant ratio of the blood concentration to the plasma concentration.</i>
--------------------	---

Description

This function calculates the constant ratio of the blood concentration to the plasma concentration.

Usage

```

calc_rblood2plasma(
  chem.cas = NULL,
  chem.name = NULL,
  dtxsid = NULL,
  parameters = NULL,
  hematocrit = NULL,
  Krbc2pu = NULL,
  Funbound.plasma = NULL,
  default.to.human = FALSE,
  species = "Human",
  adjusted.Funbound.plasma = TRUE,
  suppress.messages = TRUE
)

```

Arguments

chem.cas	Either the CAS number or the chemical name must be specified.
chem.name	Either the chemical name or the CAS number must be specified.

dtxsid	EPA's DSSTox Structure ID (https://comptox.epa.gov/dashboard) the chemical must be identified by either CAS, name, or DTXSIDs
parameters	Parameters from parameterize_schmitt
hematocrit	Overwrites default hematocrit value in calculating Rblood2plasma.
Krbc2pu	The red blood cell to unbound plasma chemical partition coefficient, typically from predict_partitioning_schmitt
Funbound.plasma	The fraction of chemical unbound (free) in the presence of plasma protein
default.to.human	Substitutes missing animal values with human values if true.
species	Species desired (either "Rat", "Rabbit", "Dog", "Mouse", or default "Human").
adjusted.Funbound.plasma	Whether or not to use Funbound.plasma adjustment.
suppress.messages	Determine whether to display certain usage feedback.

Details

The red blood cell (RBC) partition coefficient as predicted by the Schmitt (2008) method is used in the calculation. The value is calculated with the equation: $1 - \text{hematocrit} + \text{hematocrit} * \text{Krbc2pu} * \text{Funbound.plasma}$, summing the red blood cell to plasma and plasma:plasma (equal to 1) partition coefficients multiplied by their respective fractional volumes. When species is specified as rabbit, dog, or mouse, the function uses the appropriate physiological data (hematocrit and temperature), but substitutes human fraction unbound and tissue volumes.

Value

The blood to plasma chemical concentration ratio

calc_stats	Calculate toxicokinetic summary statistics (deprecated).
------------	--

Description

#' This function is included for backward compatibility. It calls `calc_tkstats` which calculates the area under the curve, the mean, and the peak values for the venous blood or plasma concentration of a specified chemical or all chemicals if none is specified for the multiple compartment model with a given number of days, dose, and number of doses per day.

Usage

```
calc_stats(  
  chem.name = NULL,  
  chem.cas = NULL,  
  dtxsid = NULL,  
  parameters = NULL,  
  route = "oral",  
  stats = c("AUC", "peak", "mean"),  
  species = "Human",  
  days = 28,  
  daily.dose = 1,  
  dose = NULL,  
  doses.per.day = 1,  
  output.units = "uM",  
  concentration = "plasma",  
  tissue = "plasma",  
  model = "pbtk",  
  default.to.human = FALSE,  
  adjusted.funbound.plasma = TRUE,  
  regression = TRUE,  
  restrictive.clearance = TRUE,  
  suppress.messages = FALSE,  
  ...  
)
```

Arguments

chem.name	Name of desired chemical.
chem.cas	CAS number of desired chemical.
dtxsid	EPA's DSSTox Structure ID (https://comptox.epa.gov/dashboard) the chemical must be identified by either CAS, name, or DTXSIDs
parameters	Chemical parameters from <code>parameterize_pbtk</code> function, overrides <code>chem.name</code> and <code>chem.cas</code> .
route	String specification of route of exposure for simulation: "oral", "iv", "inhalation", ...
stats	Desired values (either 'AUC', 'mean', 'peak', or a vector containing any combination).
species	Species desired (either "Rat", "Rabbit", "Dog", "Mouse", or default "Human").

days	Length of the simulation.
daily.dose	Total daily dose, mg/kg BW.
dose	Amount of a single dose at time zero, mg/kg BW.
doses.per.day	Number of doses per day.
output.units	Desired units (either "mg/L", "mg", "umol", or default "uM").
concentration	Desired concentration type, 'blood' or default 'plasma'.
tissue	Desired steady state tissue concentration.
model	Model used in calculation, 'pbtk' for the multiple compartment model, '3compartment' for the three compartment model, '3compartmentss' for the three compartment steady state model, and '1compartment' for one compartment model.
default.to.human	Substitutes missing animal values with human values if true (hepatic intrinsic clearance or fraction of unbound plasma).
adjusted.funbound.plasma	Uses adjusted Funbound.plasma when set to TRUE along with partition coefficients calculated with this value.
regression	Whether or not to use the regressions in calculating partition coefficients.
restrictive.clearance	Protein binding not taken into account (set to 1) in liver clearance if FALSE.
suppress.messages	Whether to suppress output message.
...	Arguments passed to solve function.

Details

Default value of 0 for doses.per.day solves for a single dose.

When species is specified as rabbit, dog, or mouse, the function uses the appropriate physiological data(volumes and flows) but substitutes human fraction unbound, partition coefficients, and intrinsic hepatic clearance.

Value

AUC	Area under the plasma concentration curve.
mean.conc	The area under the curve divided by the number of days.
peak.conc	The highest concentration.

Author(s)

Robert Pearce and John Wambaugh

calc_tkstats*Calculate toxicokinetic summary statistics.*

Description

This function calculates the area under the curve, the mean, and the peak values for the venous blood or plasma concentration of a specified chemical or all chemicals if none is specified for the multiple compartment model with a given number of days, dose, and number of doses per day.

Usage

```
calc_tkstats(  
  chem.name = NULL,  
  chem.cas = NULL,  
  dtxsid = NULL,  
  parameters = NULL,  
  route = "oral",  
  stats = c("AUC", "peak", "mean"),  
  species = "Human",  
  days = 28,  
  daily.dose = 1,  
  dose = NULL,  
  doses.per.day = 1,  
  output.units = "uM",  
  concentration = "plasma",  
  tissue = "plasma",  
  model = "pbtk",  
  default.to.human = FALSE,  
  adjusted.funbound.plasma = TRUE,  
  regression = TRUE,  
  restrictive.clearance = TRUE,  
  suppress.messages = FALSE,  
  ...  
)
```

Arguments

chem.name	Name of desired chemical.
chem.cas	CAS number of desired chemical.
dtxsid	EPA's DSSTox Structure ID (https://comptox.epa.gov/dashboard) the chemical must be identified by either CAS, name, or DTXSIDs
parameters	Chemical parameters from parameterize_pbtk function, overrides chem.name and chem.cas.
route	String specification of route of exposure for simulation: "oral", "iv", "inhalation", ...
stats	Desired values (either 'AUC', 'mean', 'peak', or a vector containing any combination).
species	Species desired (either "Rat", "Rabbit", "Dog", "Mouse", or default "Human").
days	Length of the simulation.

<code>daily.dose</code>	Total daily dose, mg/kg BW.
<code>dose</code>	Amount of a single dose at time zero, mg/kg BW.
<code>doses.per.day</code>	Number of doses per day.
<code>output.units</code>	Desired units (either "mg/L", "mg", "umol", or default "uM").
<code>concentration</code>	Desired concentration type, 'blood' or default 'plasma'.
<code>tissue</code>	Desired steady state tissue concentration.
<code>model</code>	Model used in calculation, 'pbtk' for the multiple compartment model, '3compartment' for the three compartment model, '3compartmentss' for the three compartment steady state model, and '1compartment' for one compartment model.
<code>default.to.human</code>	Substitutes missing animal values with human values if true (hepatic intrinsic clearance or fraction of unbound plasma).
<code>adjusted.funbound.plasma</code>	Uses adjusted Funbound.plasma when set to TRUE along with partition coefficients calculated with this value.
<code>regression</code>	Whether or not to use the regressions in calculating partition coefficients.
<code>restrictive.clearance</code>	Protein binding not taken into account (set to 1) in liver clearance if FALSE.
<code>suppress.messages</code>	Whether to suppress output message.
<code>...</code>	Arguments passed to solve function.

Details

Default value of 0 for `doses.per.day` solves for a single dose.

When species is specified as rabbit, dog, or mouse, the function uses the appropriate physiological data (volumes and flows) but substitutes human fraction unbound, partition coefficients, and intrinsic hepatic clearance.

Value

<code>AUC</code>	Area under the plasma concentration curve.
<code>mean.conc</code>	The area under the curve divided by the number of days.
<code>peak.conc</code>	The highest concentration.

Examples

```
calc_tkstats(chem.name='Bisphenol-A', days=100, stats='mean', model='3compartment')

calc_tkstats(chem.name='Bisphenol-A', days=100, stats=c('peak', 'mean'), species='Rat')

triclosan.stats <- calc_tkstats(days=10, chem.name = "triclosan")
```

calc_total_clearance *Calculate the total plasma clearance.*

Description

This function calculates the total clearance rate for a one compartment model for plasma where clearance is entirely due to metabolism by the liver and glomerular filtration in the kidneys, identical to clearance of three compartment steady state model.

Usage

```
calc_total_clearance(
  chem.cas = NULL,
  chem.name = NULL,
  dtxsid = NULL,
  parameters = NULL,
  species = "Human",
  suppress.messages = FALSE,
  default.to.human = FALSE,
  well.stirred.correction = TRUE,
  restrictive.clearance = TRUE,
  adjusted.funbound.plasma = TRUE,
  ...
)
```

Arguments

chem.cas	Either the chemical name, CAS number, or the parameters must be specified.
chem.name	Either the chemical name, CAS number, or the parameters must be specified.
dtxsid	EPA's 'DSSTox Structure ID (https://comptox.epa.gov/dashboard) the chemical must be identified by either CAS, name, or DTXSIDs
parameters	Chemical parameters from parameterize_steadystate function, overrides chem.name and chem.cas.
species	Species desired (either "Rat", "Rabbit", "Dog", "Mouse", or default "Human").
suppress.messages	Whether or not the output message is suppressed.
default.to.human	Substitutes missing animal values with human values if true.
well.stirred.correction	Uses correction in calculation of hepatic clearance for well-stirred model if TRUE. This assumes clearance relative to amount unbound in whole blood instead of plasma, but converted to use with plasma concentration.
restrictive.clearance	Protein binding is not taken into account (set to 1) in liver clearance if FALSE.
adjusted.funbound.plasma	Uses adjusted funbound.plasma when set to TRUE.
...	Additional parameters passed to parameterize_steadystate if parameters is NULL.

Value

Total Clearance

Units of L/h/kg BW.

Author(s)

John Wambaugh

Examples

```
calc_total_clearance(chem.name="Ibuprofen")
```

 calc_vdist

Calculate the volume of distribution for a one compartment model.

Description

This function predicts partition coefficients for all tissues, then lumps them into a single compartment.

Usage

```
calc_vdist(
  chem.cas = NULL,
  chem.name = NULL,
  dtxsid = NULL,
  parameters = NULL,
  default.to.human = FALSE,
  species = "Human",
  suppress.messages = FALSE,
  adjusted.funbound.plasma = TRUE,
  regression = TRUE,
  minimum.funbound.plasma = 1e-04
)
```

Arguments

- | | |
|------------------|---|
| chem.cas | Either the CAS number or the chemical name must be specified when Funbound.plasma is not given in parameter list. |
| chem.name | Either the chemical name or the CAS number must be specified when Funbound.plasma is not given in parameter list. |
| dtxsid | EPA's DSSTox Structure ID (https://comptox.epa.gov/dashboard) the chemical must be identified by either CAS, name, or DTXSIDs |
| parameters | Parameters from parameterize_3comp, parameterize_pbt, or predict_partitioning_schmitt. |
| default.to.human | Substitutes missing animal values with human values if true. |
| species | Species desired (either "Rat", "Rabbit", "Dog", "Mouse", or default "Human"). |

`suppress.messages` Whether or not the output message is suppressed.

`adjusted.Funbound.plasma` Uses `adjusted.Funbound.plasma` when set to TRUE along with partition coefficients calculated with this value.

`regression` Whether or not to use the regressions in calculating partition coefficients.

`minimum.Funbound.plasma` Monte Carlo draws less than this value are set equal to this value (default is 0.0001 – half the lowest measured `Fup` in our dataset).

Details

The effective volume of distribution is calculated by summing each tissues volume times it's partition coefficient relative to plasma. Plasma, and the partitioning into RBCs are also added to get the total volume of distribution in L/KG BW. Partition coefficients are calculated using Schmitt's (2008) method. When species is specified as rabbit, dog, or mouse, the function uses the appropriate physiological data(volumes and flows) but substitutes human fraction unbound, partition coefficients, and intrinsic hepatic clearance.

Value

Volume of distribution
Units of L/ kg BW.

Examples

```
calc_vdist(chem.cas="80-05-7")
calc_vdist(chem.name="Bisphenol A")
calc_vdist(chem.name="Bisphenol A",species="Rat")
```

CAS.checksum

Test the check digit of a CAS number to confirm validity

Description

Chemical abstracts services registry numbers (CAS-RN) include a final digit as a "checksum" to test for validity (that is, that the number has not been corrupted).

Usage

```
CAS.checksum(CAS.string)
```

Arguments

CAS.string A character string of three numbers separated by two dashes

Details

The check digit (final number) is calculated by working from right to left, starting with the second to last digit of the CAS-RN. We multiply each digit by an increasing digit (1, 2, 3...) and sum as we work from right to left. The check digit should equal the final digit of the sum.

Value

logical (TRUE if final digit of CAS is consistent with other digits)

chem.invivo.PK.aggregate.data

Parameter Estimates from Wambaugh et al. (2018)

Description

This table includes 1 and 2 compartment fits of plasma concentration vs time data aggregated from chem.invivo.PK.data, performed in Wambaugh et al. 2018. Data includes volume of distribution (Vdist, L/kg), elimination rate (kelim, 1/h), gut absorption rate (kgutabs, 1/h), fraction absorbed (Fgutabs), and steady state concentration (Css, mg/L).

Usage

chem.invivo.PK.aggregate.data

Format

data.frame

chem.invivo.PK.data	<i>Published toxicokinetic time course measurements</i>
---------------------	---

Description

This data set includes time and dose specific measurements of chemical concentration in tissues taken from animals administered control doses of the chemicals either orally or intravenously. This plasma concentration-time data is from rat experiments reported in public sources. Toxicokinetic data were retrieved from those studies by the Netherlands Organisation for Applied Scientific Research (TNO) using curve stripping (TechDig v2). This data is provided for statistical analysis as in Wambaugh et al. 2018.

Usage

chem.invivo.PK.data

Format

A data.frame containing 597 rows and 13 columns.

`chem.invivo.PK.summary.data`*Summary of published toxicokinetic time course experiments*

Description

This data set summarizes the time course data in the chem.invivo.PK.data table. Maximum concentration (C_{max}), time integrated plasma concentration for the duration of treatment (AUC_{treatment}) and extrapolated to zero concentration (AUC_{infinity}) as well as half-life are calculated. Summary values are given for each study and dosage. These data can be used to evaluate toxicokinetic model predictions.

Usage`chem.invivo.PK.summary.data`**Format**

A data.frame containing 100 rows and 25 columns.

chem.physical_and_invitro.data

*Physico-chemical properties and in vitro measurements for toxicokinetics***Description**

This data set contains the necessary information to make basic, high-throughput toxicokinetic (HTTK) predictions for compounds, including Funbound.plasma, molecular weight (g/mol), logP, logMA (membrane affinity), intrinsic clearance(uL/min/10⁶ cells), and pKa. These data have been compiled from multiple sources, and can be used to parameterize a variety of toxicokinetic models. See variable EPA.ref for information on the reference EPA.

Usage

chem.physical_and_invitro.data

Format

A data.frame containing 9411 rows and 54 columns.

Column Name	Description	Units
Compound	The preferred name of the chemical compound	none
CAS	The preferred Chemical Abstracts Service Registry Number	none
CAS.Checksum	A logical indicating whether the CAS number is valid	none
DTXSID	DSSTox Structure ID (http://comptox.epa.gov/dashboard)	none
Formula	The proportions of atoms within the chemical compound	none
SMILES.desalt	The simplified molecular-input line-entry system structure	none
All.Compound.Names	All names of the chemical as they occurred in the data	none
logHenry	The log10 Henry's law constant	log10(atmospheres)
logHenry.Reference	Reference for Henry's law constant	
logP	The log10 octanol:water partition coefficient (PC)	log10 unitless ratio
logP.Reference	Reference for logPow	
logPwa	The log10 water:air PC	log10 unitless ratio
logPwa.Reference	Reference for logPwa	
logMA	The log10 phospholipid:water PC or "Membrane affinity"	unitless ratio
logMA.Reference	Reference for membrane affinity	
#' logWSol	The log10 water solubility	log10(mole/L)
logWSol.Reference	Reference for logWSol	
MP	The chemical compound melting point	degrees Celsius
MP.Reference	Reference for melting point	
MW	The chemical compound molecular weight	g/mol
MW.Reference	Reference for molecular weight	
pKa_Accept	The hydrogen acceptor equilibria concentrations	logarithm
pKa_Accept.Reference	Reference for pKa_Accept	
pKa_Donor	The hydrogen acceptor equilibria concentrations	logarithm
pKa_Donor.Reference	Reference for pKa_Donor	
All.Species	All species for which data were available	none
DTXSID.Reference	Reference for DTXSID	
Formula.Reference	Reference for chemical formula	
[SPECIES].Clint	(Primary hepatocyte suspension) intrinsic hepatic clearance	uL/min/10 ⁶ hepatocytes

[SPECIES].Clint.pValue	Probability that there is no clearance observed.	none
[SPECIES].Clint.pValue.Ref	Reference for Clint pValue	
[SPECIES].Clint.Reference	Reference for Clint	
[SPECIES].Fgutabs	Fraction of chemical absorbed from the gut	unitless fraction
[SPECIES].Fgutabs.Reference	Reference for Fgutabs	
[SPECIES].Funbound.plasma	Chemical fraction unbound in presence of plasma proteins	unitless fraction
[SPECIES].Funbound.plasma.Ref	Reference for Funbound.plasma	
[SPECIES].Rblood2plasma	Chemical concentration blood to plasma ratio	unitless ratio
[SPECIES].Rblood2plasma.Ref	Reference for Rblood2plasma	
SMILES.desalt.Reference"	Reference for SMILES structure	
Chemical.Class	All classes to which the chemical has been assigned	

Details

In some cases the rapid equilibrium dialysis method (Waters et al., 2008) fails to yield detectable concentrations for the free fraction of chemical. In those cases we assume the compound is highly bound (that is, Fup approaches zero). For some calculations (for example, steady-state plasma concentration) there is precedent (Rotroff et al., 2010) for using half the average limit of detection, that is 0.005. We do not recommend using other models where quantities like partition coefficients must be predicted using Fup. We also do not recommend including the value 0.005 in training sets for Fup predictive models.

Note that in some cases the **Funbound.plasma** and the **intrinsic clearance** are *provided as a series of numbers separated by commas*. These values are the result of Bayesian analysis and characterize a distribution: the first value is the median of the distribution, while the second and third values are the lower and upper 95th percentile (that is quantile 2.5 and 97.5) respectively. For intrinsic clearance a fourth value indicating a p-value for a decrease is provided. Typically 4000 samples were used for the Bayesian analysis, such that a p-value of "0" is equivalent to "<0.00025". See Wambaugh et al. (2019) for more details.

Any one chemical compound *may have multiple ionization equilibria* (see Strobe et al., 2018) may both for donating or accepting a proton (and therefore changing charge state). If there are multiple equilibria of the same type (donor/acceptor) they are concatenated by commas.

All species-specific information is initially from experimental measurements. The functions [load_sipes2017](#), [load_pradeep2020](#), and [load_dawson2021](#) may be used to add in silico, structure-based predictions for many thousands of additional compounds to this table.

ckd_epi_eq

CKD-EPI equation for GFR.

Description

Predict GFR from serum creatinine, gender, and age.

Usage

```
ckd_epi_eq(scr, gender, reth, age_years, ckd_epi_race_coeff = FALSE)
```

Arguments

scr	Vector of serum creatinine values in mg/dL.
gender	Vector of genders (either 'Male' or 'Female').
reth	Vector of races/ethnicities. Not used unless ckd_epi_race_coeff is TRUE.
age_years	Vector of ages in years.
ckd_epi_race_coeff	Whether to use the "race coefficient" in the CKD-EPI equation. Default is FALSE.

Details

From Levey AS, Stevens LA, Schmid CH, Zhang YL, Castro AF, Feldman HI, et al. A new equation to estimate glomerular filtration rate. *Ann Intern Med* 2009; 150(9):604-612. doi:10.7326/0003-4819-150-9-200905050-00006

Value

Vector of GFR values in mL/min/1.73m².

convert_httkpop_1comp *Converts HHTK-Pop physiology into parameters relevant to the one compartment model*

Description

Converts HHTK-Pop physiology into parameters relevant to the one compartment model

Usage

convert_httkpop_1comp(parameters.dt, httkpop.dt, ...)

Arguments

parameters.dt Data table returned by [create_mc_samples](#)
httkpop.dt Data table returned by [httkpop_generate](#)
... Additional arguments passed to [propagate_invitrouv_1comp](#)

Value

A data.table whose columns are the parameters of the HTTK model specified in model.

Author(s)

Caroline Ring, John Wambaugh, and Greg Honda

References

convert_solve_x	<i>convert_solve_x</i>
-----------------	------------------------

Description

This function is designed to convert compartment values estimated from one of the HTTK models (e.g. "1compartment") using the solve_model function. It takes the HTTK model output matrix, model name, desired output units, and compound information to perform the conversion default model units to user specified units.

Usage

```
convert_solve_x(  
  model.output.mat,  
  model = NULL,  
  output.units = NULL,  
  MW = NULL,  
  vol = NULL,  
  chem.cas = NULL,  
  chem.name = NULL,  
  dtxsid = NULL,  
  parameters = NULL,  
  monitor.vars = NULL,  
  suppress.messages = FALSE,  
  verbose = FALSE,  
  ...  
)
```

Arguments

<code>model.output.mat</code>	Matrix of results from HTTK <code>solve_model</code> function.
<code>model</code>	Specified model to use in simulation: "pbtk", "3compartment", "3compartments", "1compartment", "schmitt", ...
<code>output.units</code>	Output units of interest for the compiled components. Defaults to NULL, and will provide values in model units if unspecified.
<code>MW</code>	Molecular weight of substance of interest in g/mole
<code>vol</code>	Volume for the target tissue of interest in liters (L). NOTE: Volume should not be in units of per BW, i.e. "kg".
<code>chem.cas</code>	Either the chemical name, CAS number, or the parameters must be specified.
<code>chem.name</code>	Either the chemical name, CAS number, or the parameters must be specified.
<code>dtxsid</code>	EPA's DSSTox Structure ID . (http://comptox.epa.gov/dashboard) the chemical must be identified by either CAS, name, or DTXSIDs.
<code>parameters</code>	A set of model parameters, especially a set that includes MW (molecular weight) for our conversions.
<code>monitor.vars</code>	A vector of character strings indicating the model component variables to retain in the conversion factor table (assuming <code>suppress.messages == FALSE</code>). It should also be noted this option does NOT exclude columns from the input matrix provided in the 'model.output.mat' parameter. (Default is NULL, i.e. conversion factors for all model components are included in the reporting matrix.)
<code>suppress.messages</code>	Whether or not the output messages are suppressed. (Default is FALSE, i.e. show messages.)
<code>verbose</code>	Whether or not to display the full conversion factor table. (Default is FALSE, i.e. only include rows where the conversion factor is 1.)
<code>...</code>	Other parameters that can be passed to <code>convert_units</code> , e.g. temperature and compound state. See details in convert_units .

Details

The function can be used to convert all compartments to a single unit, only units for a single model compartment, or units for a set of model compartments.

More details on the unit conversion can be found in the documentation for [convert_units](#).

Value

'new.ouput.matrix' A matrix with a column for time (in days), each compartment, and the area under the curve (AUC) and a row for each time point. The compartment and AUC columns are converted from model specified units to user specified units.

'output.units.vector' A vector of character strings providing the model compartments and their corresponding units after `convert_solve_x`.

Author(s)

Sarah E. Davidson

See Also

convert_units

Examples

```
output.mat <- solve_1comp(dt xsid = "DTXSID0020573")
new.output.mat <- convert_solve_x(output.units = "mg",
                                  model.output.mat = output.mat,
                                  model = "1compartment",
                                  dt xsid = "DTXSID0020573")
```

convert_units

*convert_units***Description**

This function is designed to accept input units, output units, and the molecular weight (MW) of a substance of interest to then use a table lookup to return a scaling factor that can be readily applied for the intended conversion. It can also take chemical identifiers in the place of a specified molecular weight value to retrieve that value for its own use.

Usage

```
convert_units(
  input.units = NULL,
  output.units = NULL,
  MW = NULL,
  vol = NULL,
  chem.cas = NULL,
  chem.name = NULL,
  dt xsid = NULL,
  parameters = NULL,
  temp = 25,
  state = "liquid"
)
```

Arguments

input.units	Assigned input units of interest
output.units	Desired output units
MW	Molecular weight of substance of interest in g/mole
vol	Volume for the target tissue of interest in liters (L). NOTE: Volume should not be in units of per BW, i.e. "kg".
chem.cas	Either the chemical name, CAS number, or the parameters must be specified.
chem.name	Either the chemical name, CAS number, or the parameters must be specified.
dt xsid	EPA's DSSTox Structure ID (http://comptox.epa.gov/dashboard) the chemical must be identified by either CAS, name, or DTXSIDs
parameters	A set of model parameters, especially a set that includes MW (molecular weight) for our conversions

temp	Temperature for conversions (default = 25 degrees C)
state	Chemical state (gas or default liquid)

Details

If input or output units not contained in the table are queried, it gives a corresponding error message. It gives a warning message about the handling of 'ppmv,' as the function is only set up to convert between ppmv and mass-based units (like mg/m^3 or umol/L) in the context of ideal gases.

convert_units is not directly configured to accept and convert units based on BW, like mg/kg . For this purpose, see [scale_dosing](#).

The function supports a limited set of most relevant units across toxicological models, currently including umol , uM , mg , mg/L , mg/m^3 or umol/L), and in the context of gases assumed to be ideal, ppmv.

Andersen and Clewell's Rules of PBPK Modeling:

- 1Check Your Units
- 2Check Your Units
- 3Check Mass Balance

Mark Sfeir, John Wambaugh, and Sarah E. Davidson

Examples

```
# MW BPA is 228.29 g/mol
# 1 mg/L -> 1/228.29*1000 = 4.38 uM
convert_units("mg/L", "uM", chem.cas="80-05-7")

# MW Diclofenac is 296.148 g/mol
# 1 uM -> 296.148/1000 = 0.296
convert_units("uM", "mg/L", chem.name="diclofenac")

convert_units("uM", "ppmv", chem.name="styrene")

# Compare with https://www3.epa.gov/ceampubl/learn2model/part-two/onsite/ia_unit_conversion.html
# 1 ug/L Toluene -> 0.263 ppmv
convert_units("ug/L", "ppmv", chem.name="toluene")
# 1 ppmv Toluene, 0.0038 mg/L
convert_units("ppmv", "mg/L", chem.name="toluene")

MW_pyrene <- get_physchem_param(param='MW', chem.name='pyrene')
conversion_factor <- convert_units(input.units='mg/L', output.units='uM',
  MW=MW_pyrene)
```

create_mc_samples

Create a table of parameter values for Monte Carlo

Description

This is the HHTK master function for creating a data table for use with Monte Carlo methods to simulate parameter uncertainty and variability. Each column of the output table corresponds to an HHTK model parameter and each row corresponds to a different random draw (for example, different individuals when considering biological variability). This function calls three different key functions to simulate parameter uncertainty and/or variability in one of three ways. First parameters can be varied in an uncorrelated manner using truncated normal distributions by the function `monte_carlo`. Then, physiological parameters can be varied in a correlated manner according to the Ring et al. (2017) ([doi:10.1016/j.envint.2017.06.004](https://doi.org/10.1016/j.envint.2017.06.004)) *httk-pop* approach by the function `httkpop_mc`. Next, both uncertainty and variability of in vitro HHTK parameters can be simulated by the function `invitro_mc` as described by Wambaugh et al. (2019) ([doi:10.1093/toxsci/kfz205](https://doi.org/10.1093/toxsci/kfz205)). Finally, tissue-specific partition coefficients are predicted for each draw using the Schmitt (2008) ([doi:10.1016/j.tiv.2007.09.010](https://doi.org/10.1016/j.tiv.2007.09.010)) method as calibrated to *in vivo* data by Pearce et al. (2017) ([doi:10.1007/s1092801795487](https://doi.org/10.1007/s1092801795487)) and implemented in `predict_partitioning_schmitt`.

Usage

```
create_mc_samples(
  chem.cas = NULL,
  chem.name = NULL,
  dtxsid = NULL,
  parameters = NULL,
  samples = 1000,
  species = "Human",
  suppress.messages = FALSE,
  model = "3compartmentss",
  httkpop = TRUE,
  invitrouv = TRUE,
  calcrb2p = TRUE,
  censored.params = list(),
  vary.params = list(),
  return.samples = FALSE,
  tissue = NULL,
  httkpop.dt = NULL,
  invitro.mc.arg.list = list(adjusted.funbound.plasma = TRUE, poormetab = TRUE,
    fup.censored.dist = FALSE, fup.lod = 0.01, fup.meas.cv = 0.4, clint.meas.cv = 0.3,
    fup.pop.cv = 0.3, clint.pop.cv = 0.3),
  httkpop.generate.arg.list = list(method = "direct resampling", gendernum = NULL,
    agelim_years = NULL, agelim_months = NULL, weight_category = c("Underweight",
    "Normal", "Overweight", "Obese"), gfr_category = c("Normal", "Kidney Disease",
    "Kidney Failure"), reths = c("Mexican American", "Other Hispanic",
    "Non-Hispanic White", "Non-Hispanic Black", "Other")),
  convert.httkpop.arg.list = list(),
  propagate.invitrouv.arg.list = list(),
  parameterize.arg.list = list(restrictive.clearance = TRUE, default.to.human = FALSE,
    clint.pvalue.threshold = 0.05, regression = TRUE)
)
```

Arguments

chem.cas	Chemical Abstract Services Registry Number (CAS-RN) – if parameters is not specified then the chemical must be identified by either CAS, name, or DTXISD
chem.name	Chemical name (spaces and capitalization ignored) – if parameters is not specified then the chemical must be identified by either CAS, name, or DTXISD
dtxsid	EPA's DSSTox Structure ID (https://comptox.epa.gov/dashboard) – if parameters is not specified then the chemical must be identified by either CAS, name, or DTXSIDs
parameters	Parameters from the appropriate parameterization function for the model indicated by argument model
samples	Number of samples generated in calculating quantiles.
species	Species desired (either "Rat", "Rabbit", "Dog", "Mouse", or default "Human"). Species must be set to "Human" to run httkpop model.
suppress.messages	Whether or not to suppress output message.
model	Model used in calculation: 'pbtk' for the multiple compartment model, '3compartment' for the three compartment model, '3compartmentss' for the three compartment steady state model, and '1compartment' for one compartment model. This only applies when httkpop=TRUE and species="Human", otherwise '3compartmentss' is used.
httkpop	Whether or not to use the Ring et al. (2017) "httkpop" population generator. Species must be 'Human'.
invitrouv	Logical to indicate whether to include in vitro parameters such as intrinsic hepatic clearance rate and fraction unbound in plasma in uncertainty and variability analysis
calcrb2p	Logical determining whether or not to recalculate the chemical ratio of blood to plasma
censored.params	The parameters listed in censored.params are sampled from a normal distribution that is censored for values less than the limit of detection (specified separately for each parameter). This argument should be a list of sub-lists. Each sublist is named for a parameter in "parameters" and contains two elements: "CV" (coefficient of variation) and "LOD" (limit of detection, below which parameter values are censored. New values are sampled with mean equal to the value in "parameters" and standard deviation equal to the mean times the CV. Censored values are sampled on a uniform distribution between 0 and the limit of detection. Not used with httkpop model.
vary.params	The parameters listed in vary.params are sampled from a normal distribution that is truncated at zero. This argument should be a list of coefficients of variation (CV) for the normal distribution. Each entry in the list is named for a parameter in "parameters". New values are sampled with mean equal to the value in "parameters" and standard deviation equal to the mean times the CV. Not used with httkpop model.
return.samples	Whether or not to return the vector containing the samples from the simulation instead of the selected quantile.
tissue	Desired steady state tissue concentration.
httkpop.dt	A data table generated by httkpop_generate . This defaults to NULL, in which case httkpop_generate is called to generate this table.

`invitro.mc.arg.list`
Additional parameters passed to `invitro_mc`.

`httkpop.generate.arg.list`
Additional parameters passed to `httkpop_generate`.

`convert.httkpop.arg.list`
Additional parameters passed to the `convert_httkpop_*` function for the model.

`propagate.invitrouv.arg.list`
Additional parameters passed to model's associated in vitro uncertainty and variability propagation function

`parameterize.arg.list`
Additional parameters passed to the `parameterize_*` function for the model.

Details

The Monte Carlo methods used here were recently updated and described by Breen et al. (submitted).

We aim to make any function that uses chemical identifiers (name, CAS, DTXSID) also work if passed a complete vector of parameters (that is, a row from the table generated by this function). This allows the use of Monte Carlo to vary the parameters and therefore vary the function output. Depending on the type of parameters (for example, physiological vs. in vitro measurements) we vary the parameters in different ways with different functions.

Value

A data table where each column corresponds to parameters needed for the specified model and each row represents a different Monte Carlo sample of parameter values.

Examples

```
sample_set = create_mc_samples(chem.name = 'bisphenol a')
```

dawson2021*Dawson et al. 2021 data*

Description

This table includes QSAR (Random Forest) model predicted values for unbound fraction plasma protein (fup) and intrinsic hepatic clearance (clint) for a subset of chemicals in the Tox21 library (see <https://www.epa.gov/chemical-research/toxicology-testing-21st-century-tox21>).

Usage

dawson2021

Format

data.frame

Details

Predictions were made with a set of Random Forest QSAR models, as reported in Dawson et al. (2021).

Author(s)

Daniel E. Dawson

Source

Dawson et al. 2021 Random Forest QSAR Model

References

EPA.ref*Reference for EPA Physico-Chemical Data*

Description

The physico-chemical data in the chem.phys_and_invitro.data table are obtained from EPA's Comp-tox Chemicals dashboard. This variable indicates the date the Dashboard was accessed.

Usage

EPA.ref

Format

An object of class character of length 1.

Author(s)

John Wambaugh

Source

estimate_gfr	<i>Predict GFR.</i>
--------------	---------------------

Description

Predict GFR using CKD-EPI equation (for adults) or BSA-based equation (for children).

Usage

```
estimate_gfr(gfrtmp.dt, gfr_resid_var = TRUE, ckd_epi_race_coeff = FALSE)
```

Arguments

gfrtmp.dt	A data.table with columns gender, reth, age_years, age_months, BSA_adj, serum_creat.
gfr_resid_var	Logical value indicating whether or not to include residual variability when generating GFR values. (Default is TRUE.)
ckd_epi_race_coeff	Logical value indicating whether or not to use the "race coefficient" from the CKD-EPI equation when estimating GFR values. (Default is FALSE.)

Details

Add residual variability based on reported residuals for each equation.

Value

The same data.table with a gfr_est column added, containing estimated GFR values.

Author(s)

Caroline Ring

References

Ring, Caroline L., et al. "Identifying populations sensitive to environmental chemicals by simulating toxicokinetic variability." Environment International 106 (2017): 105-118

estimate_gfr_ped	<i>Predict GFR in children.</i>
------------------	---------------------------------

Description

BSA-based equation from Johnson et al. 2006, Clin Pharmacokinet 45(9) 931-56. Used in Wetmore et al. 2014.

Usage

```
estimate_gfr_ped(BSA)
```

Arguments

BSA	Vector of body surface areas in m ² .
-----	--

Value

Vector of GFRs in mL/min/1.73m².

Author(s)

Caroline Ring

References

Ring, Caroline L., et al. "Identifying populations sensitive to environmental chemicals by simulating toxicokinetic variability." Environment International 106 (2017): 105-118

estimate_hematocrit	<i>Generate hematocrit values for a virtual population</i>
---------------------	--

Description

Predict hematocrit from age using smoothing splines and kernel density estimates of residual variability fitted to NHANES data, for a given combination of gender and NHANES race/ethnicity category.

Usage

```
estimate_hematocrit(gender, reth, age_years, age_months, nhanes_mec_svy)
```

Arguments

gender	Gender for which to generate hematocrit values ("Male" or "Female")
reth	NHANES race/ethnicity category for which to generate serum creatinine values ("Mexican American", "Non-Hispanic Black", "Non-Hispanic White", "Other", or "Other Hispanic")
age_years	Vector of ages in years for individuals for whom to generate hematocrit values (corresponding to age_months)
age_months	vector of ages in months for individuals for whom to generate hematocrit values (between 0-959 months)
nhanes_mec_svy	surveydesign object created from <code>mecdt</code> using <code>svydesign</code> (this is done in <code>httkpop_generate</code>)

Details

This function should usually not be called directly by the user. It is used by `httkpop_generate()` in "virtual-individuals" mode, after drawing gender, NHANES race/ethnicity category, and age from their NHANES proportions/distributions.

Value

A vector of numeric generated hematocrit values (blood percentage red blood cells by volume).

export_pbtj_jarnac	<i>Export model to jarnac.</i>
--------------------	--------------------------------

Description

This function exports the multiple compartment PBTK model to a jarnac file.

Usage

```
export_pbtj_jarnac(
  chem.cas = NULL,
  chem.name = NULL,
  species = "Human",
  initial.amounts = list(Agutlumen = 0),
  filename = "default.jan",
  digits = 4
)
```

Arguments

chem.cas	Either the chemical name or CAS number must be specified.
chem.name	Either the chemical name or CAS number must be specified.
species	Species desired (either "Rat", "Rabbit", "Dog", or default "Human").
initial.amounts	Must specify initial amounts in units of choice.
filename	The name of the jarnac file containing the model.
digits	Desired number of decimal places to round the parameters.

Details

Compartments to enter into the initial.amounts list includes Agutlumen, Aart, Aven, Alung, Agut, Aliver, Akidney, and Arest.

When species is specified as rabbit, dog, or mouse, the function uses the appropriate physiological data(volumes and flows) but substitutes human fraction unbound, partition coefficients, and intrinsic hepatic clearance.

Value

Text containing a Jarnac language version of the PBTk model.

Author(s)

Robert Pearce

Examples

```
export_pbt_k_jarnac(chem.name='Nicotine',initial.amounts=list(Agutlumen=1),filename='PBTkmodel.jan')
```

export_pbt_k_sbml	<i>Export model to sbml.</i>
-------------------	------------------------------

Description

This function exports the multiple compartment PBTk model to an sbml file.

Usage

```
export_pbt_k_sbml(
  chem.cas = NULL,
  chem.name = NULL,
  species = "Human",
  initial.amounts = list(Agutlumen = 0),
  filename = "default.xml",
  digits = 4
)
```

Arguments

chem.cas	Either the chemical name or CAS number must be specified.
chem.name	Either the chemical name or CAS number must be specified.
species	Species desired (either "Rat", "Rabbit", "Dog", or default "Human").
initial.amounts	Must specify initial amounts in units of choice.
filename	The name of the jarnac file containing the model.
digits	Desired number of decimal places to round the parameters.

Details

Compartments to enter into the initial.amounts list includes Agutlumen, Aart, Aven, Alung, Agut, Aliver, Akidney, and Arest.

When species is specified as rabbit, dog, or mouse, the function uses the appropriate physiological data(volumes and flows) but substitutes human fraction unbound, partition coefficients, and intrinsic hepatic clearance.

Value

Text describing the PBTK model in SBML.

Author(s)

Robert Pearce

Examples

```
export_pbtksbml(chem.name='Nicotine',initial.amounts=list(Agutlumen=1),filename='PBTKmodel.xml')
```

fetalpcs

Fetal Partition Coefficients

Description

Partition coefficients were measured for tissues, including placenta, in vitro by Csanady et al. (2002) for Bisphenol A and Diadzen. Curley et al. (1969) measured the concentration of a variety of pesticides in the cord blood of newborns and in the tissues of infants that were stillborn.

Usage

```
fetalpcs
```

Format

```
data.frame
```

Details

Three of the chemicals studied by Curley et al. (1969) were modeled by Weijs et al. (2013) using the same partition coefficients for mother and fetus. The values used represented "prior knowledge" summarizing the available literature.

Frank2018in vivo

Literature In Vivo Data on Doses Causing Neurological Effects

Description

Studies were selected from Table 1 in Mundy et al., 2015, as the studies in that publication were cited as examples of compounds with evidence for developmental neurotoxicity. There were sufficient in vitro toxicokinetic data available for this package for only 6 of the 42 chemicals.

Usage

Frank2018in vivo

Format

A data.frame containing 14 rows and 16 columns.

Author(s)

Timothy J. Shafer

References

Frank, Christopher L., et al. "Defining toxicological tipping points in neuronal network development." *Toxicology and Applied Pharmacology* 354 (2018): 81-93.

gen_age_height_weight *Generate demographic parameters for a virtual population*

Description

Generate gender, NHANES race/ethnicity category, ages, heights, and weights for a virtual population, based on NHANES data.

Usage

```
gen_age_height_weight(
  nsamp = NULL,
  gendernum = NULL,
  reths,
  weight_category,
  agelim_years,
  agelim_months,
  nhanes_mec_svy
)
```

Arguments

- | | |
|-----------------|---|
| nsamp | The desired number of individuals in the virtual population. nsamp need not be provided if gendernum is provided. |
| gendernum | Optional: A named list giving the numbers of male and female individuals to include in the population, e.g. <code>list(Male=100,Female=100)</code> . Default is NULL, meaning both males and females are included, in their proportions in the NHANES data. If both nsamp and gendernum are provided, they must agree (i.e., nsamp must be the sum of gendernum). |
| reths | Optional: a character vector giving the races/ethnicities to include in the population. Default is <code>c('Mexican American', 'Other Hispanic', 'Non-Hispanic White', 'Non-Hispanic Black', 'Other')</code> , to include all races and ethnicities in their proportions in the NHANES data. User-supplied vector must contain one or more of these strings. |
| weight_category | Optional: The weight categories to include in the population. Default is <code>c('Underweight', 'Normal', 'Overweight', 'Obese')</code> . User-supplied vector must contain one or more of these strings. |
| agelim_years | Optional: A two-element numeric vector giving the minimum and maximum ages (in years) to include in the population. Default is <code>c(0,79)</code> . If agelim_years is provided and agelim_months is not, agelim_years will override the default value of agelim_months. |
| agelim_months | Optional: A two-element numeric vector giving the minimum and maximum ages (in months) to include in the population. Default is <code>c(0, 959)</code> , equivalent to the default agelim_years. If agelim_months is provided and agelim_years is not, agelim_months will override the default values of agelim_years. |
| nhanes_mec_svy | surveydesign object created from <code>mecdt</code> using <code>svydesign</code> (this is done in <code>httkpop_generate</code>) |

Details

This function should usually not be called directly by the user. It is used by `httkpop_generate()` in "virtual-individuals" mode.

Value

A `data.table` containing variables

`gender` Gender of each virtual individual

`reth` Race/ethnicity of each virtual individual

`age_months` Age in months of each virtual individual

`age_years` Age in years of each virtual individual

`weight` Body weight in kg of each virtual individual

`height` Height in cm of each virtual individual

Author(s)

Caroline Ring

References

Ring, Caroline L., et al. "Identifying populations sensitive to environmental chemicals by simulating toxicokinetic variability." *Environment International* 106 (2017): 105-118

`importFrom survey svymean`

<code>gen_height_weight</code>	<i>Generate heights and weights for a virtual population.</i>
--------------------------------	---

Description

Predict height and weight from age using smoothing splines, and then add residual variability from a 2-D KDE, both fitted to NHANES data, for a given combination of gender and NHANES race/ethnicity category.

Usage

```
gen_height_weight(gender, reth, age_months, nhanes_mec_svy)
```

Arguments

`gender` Gender for which to calculate height/weight ("Male" or "Female")

`reth` NHANES race/ethnicity category for which to calculate height/weight ("Mexican American", "Non-Hispanic Black", "Non-Hispanic White", "Other", or "Other Hispanic")

`age_months` vector of ages in months for individuals for whom to calculate height/weight (between 0-959 months)

`nhanes_mec_svy` surveydesign object created from `mecdt` using `svydesign` (this is done in `httkpop_generate`)

Details

This function should usually not be called directly by the user. It is used by `httkpop_generate()` in "virtual-individuals" mode, after drawing gender, NHANES race/ethnicity category, and age from their NHANES proportions/distributions.

Value

A list containing two named elements, `weight` and `height`, each of which is a numeric vector. `weight` gives individual body weights in kg, and `height` gives individual heights in cm, corresponding to each item in the input `age_months`.

`gen_serum_creatinine` *Generate serum creatinine values for a virtual population.*

Description

Predict serum creatinine from age using smoothing splines and kernel density estimates of residual variability fitted to NHANES data,, for a given combination of gender and NHANES race/ethnicity category.

Usage

```
gen_serum_creatinine(gender, reth, age_years, age_months, nhanes_mec_svy)
```

Arguments

<code>gender</code>	Gender for which to generate serum creatinine values ("Male" or "Female")
<code>reth</code>	NHANES race/ethnicity category for which to generate serum creatinine values ("Mexican American", "Non-Hispanic Black", "Non-Hispanic White", "Other", or "Other Hispanic")
<code>age_years</code>	Vector of ages in years for individuals for whom to generate serum creatinine values (corresponding to <code>age_months</code>)
<code>age_months</code>	vector of ages in months for individuals for whom to generate serum creatinine values (between 0-959 months)
<code>nhanes_mec_svy</code>	surveydesign object created from <code>mecdt</code> using <code>svydesign</code> (this is done in <code>httkpop_generate</code>)

Details

This function should usually not be called directly by the user. It is used by `httkpop_generate()` in "virtual-individuals" mode, after drawing gender, NHANES race/ethnicity category, and age from their NHANES proportions/distributions.

Value

A vector of numeric generated serum creatinine values (mg/dL).

get_cheminfo

Retrieve chemical information from HTK package

Description

This function provides the information specified in "info=" (can be single entry or vector) for all chemicals for which a toxicokinetic model can be parameterized for a given species. Since different models have different requirements and not all chemicals have complete data, this function will return different number of chemicals depending on the model specified.

Usage

```
get_cheminfo(
  info = "CAS",
  species = "Human",
  fup.lod.default = 0.005,
  model = "3compartmentss",
  default.to.human = FALSE,
  median.only = FALSE,
  fup.ci.cutoff = TRUE,
  clint.pvalue.threshold = 0.05,
  suppress.messages = FALSE
)
```

Arguments

info	A single character vector (or collection of character vectors) from "Compound", "CAS", "DTXSID", "logP", "pKa_Donor", "pKa_Accept", "MW", "Clint", "Clint.pValue", "Funbound.plasma", "Structure_Formula", or "Substance_Type". info="all" gives all information for the model and species.
species	Species desired (either "Rat", "Rabbit", "Dog", "Mouse", or default "Human").
fup.lod.default	Default value used for fraction of unbound plasma for chemicals where measured value was below the limit of detection. Default value is 0.0005.
model	Model used in calculation, 'pbtk' for the multiple compartment model, '1compartment' for the one compartment model, '3compartment' for three compartment model, '3compartmentss' for the three compartment model without partition coefficients, or 'schmitt' for chemicals with logP and fraction unbound (used in predict_partitioning_schmitt).

default.to.human	Substitutes missing values with human values if true.
median.only	Use median values only for fup and clint. Default is FALSE.
fup.ci.cutoff	Cutoff for the level of uncertainty in fup estimates. This value should be between (0,1). Default is 'NULL' specifying no filtering.
clint.pvalue.threshold	Hepatic clearance for chemicals where the in vitro clearance assay result has a p-values greater than the threshold are set to zero.
suppress.messages	Whether or not the output messages are suppressed.

Details

When default.to.human is set to TRUE, and the species-specific data, Funbound.plasma and Clint, are missing from [chem.physical_and_invitro.data](#), human values are given instead.

In some cases the rapid equilibrium dialysis method (Waters et al., 2008) fails to yield detectable concentrations for the free fraction of chemical. In those cases we assume the compound is highly bound (that is, Fup approaches zero). For some calculations (for example, steady-state plasma concentration) there is precedent (Rotroff et al., 2010) for using half the average limit of detection, that is, 0.005 (this value is configurable via the argument fup.lod.default). We do not recommend using other models where quantities like partition coefficients must be predicted using Fup. We also do not recommend including the value 0.005 in training sets for Fup predictive models.

Note that in some cases the **Funbound.plasma** and the **intrinsic clearance** are *provided as a series of numbers separated by commas*. These values are the result of Bayesian analysis and characterize a distribution: the first value is the median of the distribution, while the second and third values are the lower and upper 95th percentile (that is quantile 2.5 and 97.5) respectively. For intrinsic clearance a fourth value indicating a p-value for a decrease is provided. Typically 4000 samples were used for the Bayesian analysis, such that a p-value of "0" is equivalent to "<0.00025". See Wambaugh et al. (2019) for more details. If argument median.only == TRUE then only the median is reported for parameters with Bayesian analysis distributions. If the 95 credible interval is larger than fup.ci.cutoff (defaults to NULL) then the Fup is treated as too uncertain and the value NA is given.

Value

vector/data.table	Table (if info has multiple entries) or vector containing a column for each valid entry specified in the argument "info" and a row for each chemical with sufficient data for the model specified by argument "model":
-------------------	--

Column	Description	units
Compound	The preferred name of the chemical compound	none
CAS	The preferred Chemical Abstracts Service Registry Number	none
DTXSID	DSSTox Structure ID (http://comptox.epa.gov/dashboard)	none
logP	The log10 octanol:water partition coefficient	log10 unitless ratio
MW	The chemical compound molecular weight	g/mol
pKa_Accept	The hydrogen acceptor equilibria concentrations	logarithm
pKa_Donor	The hydrogen donor equilibria concentrations	logarithm
[SPECIES].Clint	(Primary hepatocyte suspension) intrinsic hepatic clearance	uL/min/10 ⁶ hepatocytes
[SPECIES].Clint.pValue	Probability that there is no clearance observed.	none
[SPECIES].Funbound.plasma	Chemical fraction unbound in presence of plasma proteins	unitless fraction
[SPECIES].Rblood2plasma	Chemical concentration blood to plasma ratio	unitless ratio

```

get_chem_id	<i>Retrieve chemical identity from HTTK package</i>
-------------	---

Description

Given one of chem.name, chem.cas (Chemical Abstract Service Registry Number), or DTXSID (DSSTox Substance Identifier <https://comptox.epa.gov/dashboard>) this function checks if the chemical is available and, if so, returns all three pieces of information.

Usage

```
get_chem_id(chem.cas = NULL, chem.name = NULL, dtxsid = NULL)
```

Arguments

chem.cas	CAS registry number
chem.name	Chemical name
dtxsid	DSSTox Substance identifier

Value

A list containing the following chemical identifiers:

chem.cas	CAS registry number
chem.name	Name
dtxsid	DTXSID

Author(s)

John Wambaugh and Robert Pearce

get_gfr_category	<i>Categorize kidney function by GFR.</i>
------------------	---

Description

For adults: In general GFR > 60 is considered normal 15 < GFR < 60 is considered kidney disease GFR < 15 is considered kidney failure

Usage

```
get_gfr_category(age_years, age_months, gfr_est)
```

Arguments

age_years	Vector of ages in years.
age_months	Vector of ages in months.
gfr_est	Vector of estimated GFR values in mL/min/1.73m ² .

Details

These values can also be used for children 2 years old and greater (see PEDIATRICS IN REVIEW Vol. 29 No. 10 October 1, 2008 pp. 335-341 (doi: 10.1542/pir.29-10-335))

Value

Vector of GFR categories: 'Normal', 'Kidney Disease', 'Kidney Failure'.

get_invitroPK_param *Retrieve data from chem.physical_and_invitro.data table*

Description

or fraction unbound in plasma) from the main HTTK data. This function looks for species-specific values.

Usage

```
get_invitroPK_param(  
  param,  
  species,  
  chem.name = NULL,  
  chem.cas = NULL,  
  dtxsid = NULL  
)
```

Arguments

param	The in vitro pharmacokinetic parameter needed.
species	Species desired (either "Rat", "Rabbit", "Dog", "Mouse", or default "Human").
chem.name	Either the chemical name, CAS number, or the parameters must be specified.
chem.cas	Either the chemical name, CAS number, or the parameters must be specified.
dtxsid	EPA's DSSTox Structure ID (https://comptox.epa.gov/dashboard) the chemical must be identified by either CAS, name, or DTXSIDs

Value

The value of the parameter, if found

Author(s)

John Wambaugh and Robert Pearce

get_lit_cheminfo	<i>Get literature Chemical Information.</i>
------------------	---

Description

This function provides the information specified in "info=" for all chemicals with data from the Wetmore et al. (2012) and (2013) publications and other literature.

Usage

```
get_lit_cheminfo(info = "CAS", species = "Human")
```

Arguments

info	A single character vector (or collection of character vectors) from "Compound", "CAS", "MW", "Raw.Experimental.Percentage.Unbound", "Entered.Experimental.Percentage.Unbound", "Fub", "source_PPB", "Renal_Clearance", "Met_Stab", "Met_Stab_entered", "r2", "p.val", "Concentration.uM.", "Css_lower_5th_perc.mg.L.", "Css_median_perc.mg.L.", "Css_upper_95th_perc.mg.L.", "Css_lower_5th_perc.uM.", "Css_median_perc.uM.", "Css_upper_95th_perc.uM." and "Species".
species	Species desired (either "Rat" or default "Human").

Value

info	Table/vector containing values specified in "info" for valid chemicals.

Examples

```
get_lit_cheminfo()
get_lit_cheminfo(info=c('CAS', 'MW'))
```

get_lit_css*Get literature Css*

Description

This function retrieves a steady-state plasma concentration as a result of infusion dosing from the Wetmore et al. (2012) and (2013) publications and other literature.

Usage

```
get_lit_css(  
  chem.cas = NULL,  
  chem.name = NULL,  
  daily.dose = 1,  
  which.quantile = 0.95,  
  species = "Human",  
  clearance.assay.conc = NULL,  
  output.units = "mg/L",  
  suppress.messages = FALSE  
)
```

Arguments

chem.cas	Either the cas number or the chemical name must be specified.
chem.name	Either the chemical name or the CAS number must be specified.
daily.dose	Total daily dose infused in units of mg/kg BW/day. Defaults to 1 mg/kg/day.
which.quantile	Which quantile from the SimCYP Monte Carlo simulation is requested. Can be a vector.
species	Species desired (either "Rat" or default "Human").
clearance.assay.conc	Concentration of chemical used in measuring intrinsic clearance data, 1 or 10 uM.
output.units	Returned units for function, defaults to mg/L but can also be uM (specify units = "uM").
suppress.messages	Whether or not the output message is suppressed.

Value

A numeric vector with the literature steady-state plasma concentration (1 mg/kg/day) for the requested quantiles

"Incorporating High-Throughput Exposure Predictions with Dosimetry-Adjusted In Vitro Bioactivity to Inform Chemical Toxicity Testing" *Toxicological Sciences*, kfv171.

Examples

```
get_lit_css(chem.cas="34256-82-1")

get_lit_css(chem.cas="34256-82-1", species="Rat", which.quantile=0.5)

get_lit_css(chem.cas="80-05-7", daily.dose = 1, which.quantile = 0.5, output.units = "uM")
```

get_lit_oral_equiv	<i>Get Literature Oral Equivalent Dose</i>
--------------------	--

Description

This function converts a chemical plasma concentration to an oral equivalent dose using the values from the Wetmore et al. (2012) and (2013) publications and other literature.

Usage

```
get_lit_oral_equiv(
  conc,
  chem.name = NULL,
  chem.cas = NULL,
  dtxsid = NULL,
  suppress.messages = FALSE,
  which.quantile = 0.95,
  species = "Human",
  input.units = "uM",
  output.units = "mg",
  clearance.assay.conc = NULL,
  ...
)
```

Arguments

conc	Bioactive in vitro concentration in units of specified input.units, default of uM.
chem.name	Either the chemical name or the CAS number must be specified.
chem.cas	Either the CAS number or the chemical name must be specified.
dtxsid	EPA's 'DSSTox Structure ID (https://comptox.epa.gov/dashboard) the chemical must be identified by either CAS, name, or DTXSIDs
suppress.messages	Suppress output messages.
which.quantile	Which quantile from the SimCYP Monte Carlo simulation is requested. Can be a vector. Papers include 0.05, 0.5, and 0.95 for humans and 0.5 for rats.
species	Species desired (either "Rat" or default "Human").
input.units	Units of given concentration, default of uM but can also be mg/L.
output.units	Units of dose, default of 'mg' for mg/kg BW/ day or 'mol' for mol/ kg BW/ day.
clearance.assay.conc	Concentration of chemical used in measuring intrinsic clearance data, 1 or 10 uM.
...	Additional parameters passed to get_lit_css.

Value

Equivalent dose in specified units, default of mg/kg BW/day.

```

get_physchem_param	<i>Get physico-chemical parameters from chem.physical_and_invitro.data</i>
--------------------	--

Description

This function retrieves physico-chemical properties ("param") for the chemical specified by chem.name or chem.cas from the vLiver tables.

Usage

```
get_physchem_param(param, chem.name = NULL, chem.cas = NULL, dtxsid = NULL)
```

Arguments

param	The desired parameters, a vector or single value.
chem.name	The chemical names that you want parameters for, a vector or single value
chem.cas	The chemical CAS numbers that you want parameters for, a vector or single value
dtxsid	EPA's 'DSSTox Structure ID (https://comptox.epa.gov/dashboard) the chemical must be identified by either CAS, name, or DTXSIDs

Value

The parameters, either a single value, a named list for a single chemical, or a list of lists

Author(s)

John Wambaugh and Robert Pearce

Examples

```
get_physchem_param(param = 'logP', chem.cas = '80-05-7')
get_physchem_param(param = c('logP', 'MW'), chem.cas = c('80-05-7', '81-81-2'))
```

get_rblood2plasma	<i>Get ratio of the blood concentration to the plasma concentration.</i>
-------------------	--

Description

This function attempts to retrieve a measured species- and chemical-specific blood:plasma concentration ratio.

Usage

```
get_rblood2plasma(  
  chem.name = NULL,  
  chem.cas = NULL,  
  dtxsid = NULL,  
  species = "Human",  
  default.to.human = FALSE  
)
```

Arguments

chem.name	Either the chemical name or the CAS number must be specified.
chem.cas	Either the CAS number or the chemical name must be specified.
dtxsid	EPA's 'DSSTox Structure ID (https://comptox.epa.gov/dashboard) the chemical must be identified by either CAS, name, or DTXSIDs
species	Species desired (either "Rat", "Rabbit", "Dog", "Mouse", or default "Human").
default.to.human	Substitutes missing animal values with human values if true.

Details

A value of NA is returned when the requested value is unavailable. Values are retrieved from chem.physical_and_invitro.data. details than the description above ~~

Value

A numeric value for the steady-state ratio of chemical concentration in blood to plasma

Author(s)

Robert Pearce

Examples

```
get_rblood2plasma(chem.name="Bisphenol A")  
get_rblood2plasma(chem.name="Bisphenol A",species="Rat")
```

get_weight_class	<i>Assign weight class (underweight, normal, overweight, obese)</i>
------------------	---

Description

Given vectors of age, BMI, recumbent length, weight, and gender, categorizes weight classes using CDC and WHO categories.

Usage

```
get_weight_class(age_years, age_months, bmi, recumlen, weight, gender)
```

Arguments

age_years	A vector of ages in years.
age_months	A vector of ages in months.
bmi	A vector of BMIs.
recumlen	A vector of heights or recumbent lengths in cm.
weight	A vector of body weights in kg.
gender	A vector of genders (as 'Male' or 'Female').

Details

According to the CDC (<https://www.cdc.gov/obesity/basics/adult-defining.html>), adult weight classes are defined using BMI as follows:

Underweight BMI less than 18.5

Normal BMI between 18.5 and 25

Overweight BMI between 25 and 30

Obese BMI greater than 30

For children ages 2 years and older, weight classes are defined using percentiles of sex-specific BMI for age, as follows (Barlow et al., 2007):

Underweight Below 5th percentile BMI for age

Normal 5th-85th percentile BMI for age

Overweight 85th-95th percentile BMI for age

Obese Above 95th percentile BMI for age

For children birth to age 2, weight classes are defined using percentiles of sex-specific weight-for-length (Grummer-Strawn et al., 2009). Weight above the 97.7th percentile, or below the 2.3rd percentile, of weight-for-length is considered potentially indicative of adverse health conditions. Here, weight below the 2.3rd percentile is categorized as "Underweight" and weight above the 97.7th percentile is categorized as "Obese."

Value

A character vector of weight classes. Each element will be one of 'Underweight', 'Normal', 'Overweight', or 'Obese'.

Examples

```
get_lit_cheminfo()
get_lit_cheminfo(info=c('CAS', 'MW'))
```

get_wetmore_css	<i>Get literature C_{ss} (deprecated).</i>
-----------------	--

Description

This function is included for backward compatibility. It calls [get_lit_css](#) which retrieves a steady-state plasma concentration as a result of infusion dosing from the Wetmore et al. (2012) and (2013) publications and other literature.

Usage

```
get_wetmore_css(
  chem.cas = NULL,
  chem.name = NULL,
  daily.dose = 1,
  which.quantile = 0.95,
  species = "Human",
  clearance.assay.conc = NULL,
  output.units = "mg/L",
  suppress.messages = FALSE
)
```

Arguments

chem.cas	Either the cas number or the chemical name must be specified.
chem.name	Either the chemical name or the CAS number must be specified.
daily.dose	Total daily dose infused in units of mg/kg BW/day. Defaults to 1 mg/kg/day.
which.quantile	Which quantile from the SimCYP Monte Carlo simulation is requested. Can be a vector.

species Species desired (either "Rat" or default "Human").

clearance.assay.conc Concentration of chemical used in measuring intrinsic clearance data, 1 or 10 uM.

output.units Returned units for function, defaults to mg/L but can also be uM (specify units = "uM").

suppress.messages Whether or not the output message is suppressed.

Value

A numeric vector with the literature steady-state plasma concentration (1 mg/kg/day) for the requested quantiles

```

```
get_lit_css(chem.cas="80-05-7", daily.dose = 1, which.quantile = 0.5, output.units = "uM")
```

```
get_wetmore_oral_equiv
```

Get Literature Oral Equivalent Dose (deprecated).

Description

This function is included for backward compatibility. It calls [get_lit_oral_equiv](#) which converts a chemical plasma concentration to an oral equivalent dose using the values from the Wetmore et al. (2012) and (2013) publications and other literature.

Usage

```
get_wetmore_oral_equiv(
  conc,
  chem.name = NULL,
  chem.cas = NULL,
  suppress.messages = FALSE,
  which.quantile = 0.95,
  species = "Human",
  input.units = "uM",
  output.units = "mg",
  clearance.assay.conc = NULL,
  ...
)
```

Arguments

conc	Bioactive in vitro concentration in units of specified input.units, default of uM.
chem.name	Either the chemical name or the CAS number must be specified.
chem.cas	Either the CAS number or the chemical name must be specified.
suppress.messages	Suppress output messages.
which.quantile	Which quantile from the SimCYP Monte Carlo simulation is requested. Can be a vector. Papers include 0.05, 0.5, and 0.95 for humans and 0.5 for rats.
species	Species desired (either "Rat" or default "Human").
input.units	Units of given concentration, default of uM but can also be mg/L.
output.units	Units of dose, default of 'mg' for mg/kg BW/ day or 'mol' for mol/ kg BW/ day.
clearance.assay.conc	Concentration of chemical used in measuring intrinsic clearance data, 1 or 10 uM.
...	Additional parameters passed to get_lit_css.

Value

Equivalent dose in specified units, default of mg/kg BW/day.

hct_h

KDE bandwidths for residual variability in hematocrit

Description

Bandwidths used for a one-dimensional kernel density estimation of the distribution of residual errors around smoothing spline fits of hematocrit vs. age for NHANES respondents in each of ten combinations of sex and race/ethnicity categories.

Usage

```
hct_h
```

Format

A named list with 10 elements, each a numeric value. Each list element corresponds to, and is named for, one combination of NHANES sex categories (Male and Female) and NHANES race/ethnicity categories (Mexican American, Other Hispanic, Non-Hispanic White, Non-Hispanic Black, and Other).

Details

Each matrix is the standard deviation for a normal distribution: this is the bandwidth to be used for a kernel density estimation (KDE) (using a normal kernel) of the distribution of residual errors around smoothing spline fits of hematocrit vs. age for NHANES respondents in the specified sex and race/ethnicity category. Optimal bandwidths were pre-calculated by doing the smoothing spline fits, getting the residuals, then calling `kde` on the residuals (which calls `hpi` to compute the plug-in bandwidth).

Used by HHTK-Pop only in "virtual individuals" mode (i.e. `httkpop_generate` with `method = "v"`), in `estimate_hematocrit`.

hematocrit_infants	<i>Predict hematocrit in infants under 1 year old.</i>
--------------------	--

Description

For infants under 1 year, hematocrit was not measured in NHANES. Assume a log-normal distribution where plus/minus 1 standard deviation of the underlying normal distribution is given by the reference range. Draw hematocrit values from these distributions by age.

Usage

```
hematocrit_infants(age_months)
```

Arguments

age_months Vector of ages in months; all must be ≤ 12 .

Details

Age	Reference range
<1 month	31-49
1-6 months	29-42
7-12 months	33-38

Value

Vector of hematocrit percentages corresponding to the input vector of ages.

honda.ivive

*Return the assumptions used in Honda et al. 2019***Description**

This function returns four of the better performing sets of assumptions evaluated in Honda et al. 2019 (<https://doi.org/10.1371/journal.pone.0217564>). These include four different combinations of hepatic clearance assumption, in vivo bioactivity assumption, and relevant tissue assumption. Generally, this function is not called directly by the user, but instead called by setting the IVIVE option in `calc_mc_oral_equiv`, `calc_mc_css`, and `calc_analytic` functions. Currently, these IVIVE option is not implemented the `solve_1comp` etc. functions.

Usage

```
honda.ivive(method = "Honda1", tissue = "liver")
```

Arguments

<code>method</code>	This is set to one of "Honda1", "Honda2", "Honda3", or "Honda4".
<code>tissue</code>	This is only relevant to "Honda4" and indicates the relevant tissue compartment.

Details

"Honda1" - `tissue = NULL`, `restrictive.clearance = TRUE`, `bioactive.free.invivo = TRUE` This assumption assumes restrictive hepatic clearance, and treats the free concentration in plasma as the bioactive concentration in vivo. This option must be used in combination with the concentration in vitro predicted by `armitage_eval()`, otherwise the result will be the same as "Honda2". This option corresponds to the result in Figure 8 panel c) restrictive, mean free plasma conc., Armitage in Honda et al. 2019. "Honda2" - `tissue = NULL`, `restrictive.clearance = TRUE`, `bioactive.free.invivo = TRUE` This assumption assumes restrictive hepatic clearance, and treats the free concentration in plasma as the bioactive concentration in vivo. This option corresponds to the result in Figure 8 panel b) restrictive, mean free plasma conc. in Honda et al. 2019. "Honda3" - `tissue = NULL`, `restrictive.clearance = TRUE`, `bioactive.free.invivo = TRUE` This assumption assumes restrictive hepatic clearance, and treats the free concentration in plasma as the bioactive concentration in vivo. This option corresponds to the result in Figure 8 panel a) restrictive, mean total plasma conc. in Honda et al. 2019. "Honda4" - `tissue = tissue`, `restrictive.clearance = FALSE`, `bioactive.free.invivo = TRUE` This assumption assumes restrictive hepatic clearance, and treats the free concentration in plasma as the bioactive concentration in vivo. The input tissue should be relevant to the in vitro assay endpoint used as input or that the result is being compared to. This option corresponds to the result in Figure 8 panel d) nonrestrictive, mean tissue conc. in Honda et al. 2019.

Value

A list of `tissue`, `bioactive.free.invivo`, and `restrictive.clearance` assumptions.

httkpop	<i>httkpop: Virtual population generator for HTK.</i>
---------	---

Description

The httkpop package generates virtual population physiologies for use in population TK.

Details

To simulate inter-individual variability in the TK model, a MC approach is used: the model parameters are sampled from known or assumed distributions, and the model is evaluated for each sampled set of parameters. To simulate variability across subpopulations, the MC approach needs to capture the parameter correlation structure. For example, kidney function changes with age (Levey et al., 2009), thus the distribution of GFR is likely different in 6-year-olds than in 65-year-olds. To directly measure the parameter correlation structure, all parameters need to be measured in each individual in a representative sample population. Such direct measurements are extremely limited. However, the correlation structure of the physiological parameters can be inferred from their known individual correlations with demographic and anthropometric quantities for which direct population measurements do exist. These quantities are sex, race/ethnicity, age, height, and weight (Howgate et al., 2006; Jamei et al., 2009a; Johnson et al., 2006; McNally et al., 2014; Price et al., 2003). Direct measurements of these quantities in a large, representative sample of the U.S. population are publicly available from NHANES. NHANES also includes laboratory measurements, including both serum creatinine, which can be used to estimate GFR (Levey et al., 2009), and hematocrit. For conciseness, sex, race/ethnicity, age, height, weight, serum creatinine, and hematocrit will be called the NHANES quantities.

HTTK-Pop's correlated MC approach begins by sampling from the joint distribution of the NHANES quantities to simulate a population. Then, for each individual in the simulated population, HTTK-Pop predicts the physiological parameters from the NHANES quantities using regression equations from the literature (Barter et al., 2007; Baxter-Jones et al., 2011; Bosgra et al., 2012; Koo et al., 2000; Levey et al., 2009; Looker et al., 2013; McNally et al., 2014; Ogiu et al., 1997; Price et al., 2003; Schwartz and Work, 2009; Webber and Barr 2012). Correlations among the physiological parameters are induced by their mutual dependence on the correlated NHANES quantities. Finally, residual variability is added to the predicted physiological parameters using estimates of residual marginal variance (i.e., variance not explained by the regressions on the NHANES quantities) (McNally et al., 2014).

Data were combined from the three most recent publicly-available NHANES cycles: 2007-2008, 2009-2010, and 2011-2012. For each cycle, some NHANES quantities - height, weight, serum creatinine, and hematocrit - were measured only in a subset of respondents. Only these subsets were included in HTTK-Pop. The pooled subsets from the three cycles contained 29,353 unique respondents. Some respondents were excluded from analysis: those with age recorded as 80 years (because all NHANES respondents 80 years and older were marked as "80"); those with missing height, weight or hematocrit data; and those aged 12 years or older with missing serum creatinine data. These criteria excluded 4807 respondents, leaving 24,546 unique respondents. Each NHANES respondent was assigned a cycle-specific sample weight, which can be interpreted as the number of individuals in the total U.S. population represented by each NHANES respondent in each cycle (Johnson et al., 2013). Because data from three cycles were combined, the sample weights were rescaled (divided by the number of cycles being combined, as recommended in NHANES data analysis documentation) (Johnson et al., 2013). To handle the complex NHANES sampling structure, the R survey package was used to analyze the NHANES data (Lumley, 2004).

To allow generation of virtual populations specified by weight class, we coded a categorical variable for each NHANES respondent. The categories Underweight, Normal, Overweight, or Obese were assigned based on weight, age, and height/length (Grummer-Strawn et al., 2010; Kuczmarski et al., 2002; Ogden et al., 2014; WHO, 2006, 2010). We implemented two population simulation methods within HTTK-Pop: the direct-resampling method and the virtual-individuals method. The direct-resampling method simulated a population by sampling NHANES respondents with replacement, with probabilities proportional to the sample weights. Each individual in the resulting simulated population was an NHANES respondent, identified by a unique NHANES sequence number. By contrast, the second method generates "virtual individuals" - sets of NHANES quantities that obey the approximate joint distribution of the NHANES quantities (calculated using weighted smooth-

ing functions and kernel density estimators), but do not necessarily correspond to any particular NHANES respondent. The direct-resampling method removed the possibility of generating unrealistic combinations of the NHANES quantities; the virtual-individuals method allowed the use of interpolation to simulate subpopulations represented by only a small number of NHANES respondents.

For either method, HTTK-Pop takes optional specifications about the population to be simulated and then samples from the appropriate conditional joint distribution of the NHANES quantities.

Once HTTK-Pop has simulated a population characterized by the NHANES quantities, the physiological parameters of the TK model are predicted from the NHANES quantities using regression equations from the literature. Liver mass was predicted for individuals over age 18 using allometric scaling with height from Reference Man (Valentin, 2002), and for individuals under 18 using regression relationships with height and weight published by Ogiu et al. (1997). Residual marginal variability was added for each individual as in PopGen (McNally et al., 2014). Similarly, hepatic portal vein blood flows (in L/h) are predicted as fixed fractions of a cardiac output allometrically scaled with height from Reference Man (Valentin, 2002), and residual marginal variability is added for each individual (McNally et al., 2014). Glomerular filtration rate (GFR) (in L/h/1.73 m² body surface area) is predicted from age, race, sex, and serum creatinine using the CKD-EPI equation, for individuals over age 18 (Levey et al., 2009). For individuals under age 18, GFR is estimated from body surface area (BSA) (Johnson et al., 2006); BSA is predicted using Mosteller's formula (Verbraecken et al., 2006) for adults and Haycock's formula (Haycock et al., 1978) for children. Hepatocellularity (in millions of cells per gram of liver tissue) is predicted from age using an equation developed by Barter et al. (2007). Hematocrit is estimated from NHANES data for individuals 1 year and older. For individuals younger than 1 year, for whom NHANES did not measure hematocrit directly, hematocrit was predicted from age in months, using published reference ranges (Lubin, 1987).

In addition to the HTTK physiological parameters, the HTTK models include chemical-specific parameters representing the fraction of chemical unbound in plasma (Fup) and intrinsic clearance (CL_{int}). Because these parameters represent interactions of the chemical with the body, their values will vary between individuals. To simulate this variability, Fup and CL_{int} were included in MC simulations, by sampling from estimated or assumed distributions for the parameters defining them.

Variability in hematocrit was simulated either using NHANES data (for individuals ages 1 and older) or using age-based reference ranges (for individuals under age 1). Fup was treated as a random variable obeying a distribution censored below the average limit of quantification (LOQ) of the in vitro assay. Specifically, Fup was assumed to obey a normal distribution truncated below at 0 and above at 1, centered at the Fup value measured in vitro, with a 30 the average LOQ (0.01), Fup was instead drawn from a uniform distribution between 0 and 0.01. Fup was assumed to be independent of all other parameters. This censored normal distribution was chosen to match that used in Wambaugh et al. (2015).

Variability in hepatocellularity (106 cells/g liver) and M_{liver} (kg) were simulated. The remaining source of variability in CL_{int,h} is variability in CL_{int}, which was simulated using a Gaussian mixture distribution to represent the population proportions of poor metabolizers (PMs) and non-PMs of each substance. The true prevalence of PMs is isozyme-specific (Ma et al., 2002; Yasuda et al., 2008); however, isozyme-specific metabolism data were not available for the majority of chemicals considered. We therefore made a simplifying assumption that 5 slower than average. With 95 a normal distribution truncated below at zero, centered at the value measured in vitro, with a 30 CL_{int} was drawn from a PM distribution: a truncated normal distribution centered on one-tenth of the in vitro value with 30 Both CL_{int} itself and the probability of being a PM were assumed to be independent of all other parameters. The truncated normal nonePM distribution was chosen because it has been used (with 100 in previous work (Rotroff et al., 2010; Wambaugh et al., 2015; Wetmore et al., 2014; Wetmore et al., 2015; Wetmore et al., 2012); the PM distribution was chosen to comport with the nonePM distribution.

Main function to generate a population

If you just want to generate a table of (chemical-independent) population physiology parameters, use [httkpop_generate](#).

Using HTTK-Pop with HTTK

To generate a population and then run an HTTK model for that population, the workflow is as follows:

1. Generate a population using [httkpop_generate](#).
2. For a given HTTK chemical and general model, convert the population data to corresponding sets of HTTK model parameters using [httkpop_mc](#).

httkpop_biotophys_default

Convert HTTK-Pop-generated parameters to HTTK physiological parameters

Description

Convert HTTK-Pop-generated parameters to HTTK physiological parameters

Usage

```
httkpop_biotophys_default(indiv_dt)
```

Arguments

`indiv_dt` The data.table object returned by `httkpop_generate()`

Value

A data.table with the physiological parameters expected by any HTTK model, including body weight (BW), hematocrit, tissue volumes per kg body weight, tissue flows as fraction of CO, CO per (kg BW)^{3/4}, GFR per (kg BW)^{3/4}, portal vein flow per (kg BW)^{3/4}, and liver density.

httkpop_direct_resample

Generate a virtual population by directly resampling the NHANES data.

Description

Generate a virtual population by directly resampling the NHANES data.

Usage

```
httkpop_direct_resample(
  nsamp = NULL,
  gendernum = NULL,
  agelim_years = NULL,
  agelim_months = NULL,
  weight_category = c("Underweight", "Normal", "Overweight", "Obese"),
  gfr_category = c("Normal", "Kidney Disease", "Kidney Failure"),
  reths = c("Mexican American", "Other Hispanic", "Non-Hispanic White",
    "Non-Hispanic Black", "Other"),
  gfr_resid_var = TRUE,
  ckd_epi_race_coeff = FALSE,
  nhanes_mec_svy
)
```

Arguments

nsamp	The desired number of individuals in the virtual population. nsamp need not be provided if gendernum is provided.
gendernum	Optional: A named list giving the numbers of male and female individuals to include in the population, e.g. <code>list(Male=100,Female=100)</code> . Default is NULL, meaning both males and females are included, in their proportions in the NHANES data. If both nsamp and gendernum are provided, they must agree (i.e., nsamp must be the sum of gendernum).
agelim_years	Optional: A two-element numeric vector giving the minimum and maximum ages (in years) to include in the population. Default is <code>c(0,79)</code> . If agelim_years is provided and agelim_months is not, agelim_years will override the default value of agelim_months.
agelim_months	Optional: A two-element numeric vector giving the minimum and maximum ages (in months) to include in the population. Default is <code>c(0, 959)</code> , equivalent to the default agelim_years. If agelim_months is provided and agelim_years is not, agelim_months will override the default values of agelim_years.
weight_category	Optional: The weight categories to include in the population. Default is <code>c('Underweight', 'Normal', 'Overweight', 'Obese')</code> . User-supplied vector must contain one or more of these strings.
gfr_category	The kidney function categories to include in the population. Default is <code>c('Normal', 'Kidney Disease', 'Kidney Failure')</code> to include all kidney function levels.

reths	Optional: a character vector giving the races/ethnicities to include in the population. Default is <code>c('Mexican American', 'Other Hispanic', 'Non-Hispanic White', 'Non-Hispanic Black', 'Other')</code> , to include all races and ethnicities in their proportions in the NHANES data. User-supplied vector must contain one or more of these strings.
gfr_resid_var	Logical value indicating whether or not to include residual variability when generating GFR values. (Default is TRUE.)
ckd_epi_race_coeff	Logical value indicating whether or not to use the "race coefficient" from the CKD-EPI equation when estimating GFR values. (Default is FALSE.)
nhanes_mec_svy	surveydesign object created from <code>mecdt</code> using <code>svydesign</code> (this is done in <code>httkpop_generate</code>)

Value

A `data.table` where each row represents an individual, and each column represents a demographic, anthropometric, or physiological parameter.

httkpop_direct_resample_inner

Inner loop function called by httkpop_direct_resample.

Description

Inner loop function called by `httkpop_direct_resample`.

Usage

```
httkpop_direct_resample_inner(
  nsamp,
  gendernum,
  agelim_months,
  agelim_years,
  reths,
  weight_category,
  gfr_resid_var,
  ckd_epi_race_coeff,
  nhanes_mec_svy
)
```

Arguments

<code>nsamp</code>	The desired number of individuals in the virtual population. <code>nsamp</code> need not be provided if <code>gendernum</code> is provided.
<code>gendernum</code>	Optional: A named list giving the numbers of male and female individuals to include in the population, e.g. <code>list(Male=100,Female=100)</code> . Default is <code>NULL</code> , meaning both males and females are included, in their proportions in the NHANES data. If both <code>nsamp</code> and <code>gendernum</code> are provided, they must agree (i.e., <code>nsamp</code> must be the sum of <code>gendernum</code>).
<code>agelim_months</code>	Optional: A two-element numeric vector giving the minimum and maximum ages (in months) to include in the population. Default is <code>c(0, 959)</code> , equivalent to the default <code>agelim_years</code> . If <code>agelim_months</code> is provided and <code>agelim_years</code> is not, <code>agelim_months</code> will override the default values of <code>agelim_years</code> .
<code>agelim_years</code>	Optional: A two-element numeric vector giving the minimum and maximum ages (in years) to include in the population. Default is <code>c(0,79)</code> . If <code>agelim_years</code> is provided and <code>agelim_months</code> is not, <code>agelim_years</code> will override the default value of <code>agelim_months</code> .
<code>reths</code>	Optional: a character vector giving the races/ethnicities to include in the population. Default is <code>c('Mexican American', 'Other Hispanic', 'Non-Hispanic White', 'Non-Hispanic Black', 'Other')</code> , to include all races and ethnicities in their proportions in the NHANES data. User-supplied vector must contain one or more of these strings.
<code>weight_category</code>	Optional: The weight categories to include in the population. Default is <code>c('Underweight', 'Normal', 'Overweight', 'Obese')</code> . User-supplied vector must contain one or more of these strings.
<code>gfr_resid_var</code>	Logical value indicating whether or not to include residual variability when generating GFR values. (Default is <code>TRUE</code> , passed from <code>'httkpop_direct_resample'</code> .)
<code>ckd_epi_race_coeff</code>	Logical value indicating whether or not to use the "race coefficient" from the CKD-EPI equation when estimating GFR values. (Default is <code>FALSE</code> , passed from <code>'httkpop_direct_resample'</code> .)
<code>nhanes_mec_svy</code>	surveydesign object created from <code>mecdt</code> using <code>svydesign</code> (this is done in <code>httkpop_generate</code>)

Value

A `data.table` where each row represents an individual, and each column represents a demographic, anthropometric, or physiological parameter.

httkpop_generate	<i>Generate a virtual population for PBTK</i>
------------------	---

Description

Generate a virtual population characterized by demographic, anthropometric, and physiological parameters relevant to PBTK.

Usage

```
httkpop_generate(
  method,
  nsamp = NULL,
  gendernum = NULL,
  agelim_years = NULL,
  agelim_months = NULL,
  weight_category = c("Underweight", "Normal", "Overweight", "Obese"),
  gfr_category = c("Normal", "Kidney Disease", "Kidney Failure"),
  reths = c("Mexican American", "Other Hispanic", "Non-Hispanic White",
    "Non-Hispanic Black", "Other"),
  gfr_resid_var = TRUE,
  ckd_epi_race_coeff = FALSE
)
```

Arguments

method	The population-generation method to use. Either "virtual individuals" or "direct resampling." Short names may be used: "d" or "dr" for "direct resampling", and "v" or "vi" for "virtual individuals".
nsamp	The desired number of individuals in the virtual population. nsamp need not be provided if gendernum is provided.
gendernum	Optional: A named list giving the numbers of male and female individuals to include in the population, e.g. <code>list(Male=100,Female=100)</code> . Default is NULL, meaning both males and females are included, in their proportions in the NHANES data. If both nsamp and gendernum are provided, they must agree (i.e., nsamp must be the sum of gendernum).
agelim_years	Optional: A two-element numeric vector giving the minimum and maximum ages (in years) to include in the population. Default is <code>c(0,79)</code> . If only a single value is provided, both minimum and maximum ages will be set to that value; e.g. <code>agelim_years=3</code> is equivalent to <code>agelim_years=c(3,3)</code> . If <code>agelim_years</code> is provided and <code>agelim_months</code> is not, <code>agelim_years</code> will override the default value of <code>agelim_months</code> .
agelim_months	Optional: A two-element numeric vector giving the minimum and maximum ages (in months) to include in the population. Default is <code>c(0, 959)</code> , equivalent to the default <code>agelim_years</code> . If only a single value is provided, both minimum and maximum ages will be set to that value; e.g. <code>agelim_months=36</code> is equivalent to <code>agelim_months=c(36,36)</code> . If <code>agelim_months</code> is provided and <code>agelim_years</code> is not, <code>agelim_months</code> will override the default values of <code>agelim_years</code> .

weight_category	Optional: The weight categories to include in the population. Default is c('Underweight', 'Normal', 'Overweight', 'Obese'). User-supplied vector must contain one or more of these strings.
gfr_category	The kidney function categories to include in the population. Default is c('Normal', 'Kidney Disease', 'Kidney Failure') to include all kidney function levels.
reth	Optional: a character vector giving the races/ethnicities to include in the population. Default is c('Mexican American', 'Other Hispanic', 'Non-Hispanic White', 'Non-Hispanic Black', 'Other'), to include all races and ethnicities in their proportions in the NHANES data. User-supplied vector must contain one or more of these strings.
gfr_resid_var	TRUE to add residual variability to GFR predicted from serum creatinine; FALSE to not add residual variability
ckd_epi_race_coeff	TRUE to use the CKD-EPI equation as originally published (with a coefficient changing predicted GFR for individuals identified as "Non-Hispanic Black"); FALSE to set this coefficient to 1.

Details

Demographic and anthropometric (body measures) variables, along with serum creatinine and hematocrit, are generated from survey data from the Centers for Disease Control’s National Health and Nutrition Examination Survey (NHANES). Those data are stored in the object `nhanes_mec_svy` (a `survey.design` object, see package `survey`). With `method = "d"`, these variables will be sampled with replacement directly from NHANES data. Each NHANES respondent’s likelihood of being sampled is given by their sample weight. With `method = "v"`, these variables will be sampled from distributions fitted to NHANES data. Tissue masses and flows are generated based on demographic, body measures, and serum creatinine values, using regression equations from the literature and/or allometric scaling based on height. Extensive details about how each of these parameters are generated are available in the supplemental material of Ring et al. (2017) (see References for full citation).

Value

A `data.table` where each row represents an individual, and each column represents a demographic, anthropometric, or physiological parameter. Details of the parameters returned and their units are in the following tables.

Demographic variables

Name	D
seqn	NHANES unique identifier (only included if <code>method = "direct resampling"</code>)
gender	Sex: "Male" or "Female"
reth	Race/ethnicity: "Non-Hispanic Black", "Non-Hispanic white", "Mexican American", "Other Hispanic", or "Other"
age_years	Age (0-74)
age_months	Age (0-959)

Body measures and laboratory measurements

Name	Definition	Units
height	Height	cm
weight	Body weight	kg
serum_creat	Serum creatinine	mg/dL
hematocrit	Hematocrit (percentage by volume of red blood cells in blood)	%

Tissue masses

Name	Definition	Units
Blood_mass		Mass of blood
Brain_mass		Mass of brain
Gonads_mass		Mass of gonads
Heart_mass		Mass of heart
Kidneys_mass		Mass of kidneys
Large_intestine_mass		Mass of large intestine
Liver_mass		Mass of liver
Lung_mass		Mass of lung
Muscle_mass		Mass of muscle
Pancreas_mass		Mass of pancreas
Skeleton_mass	Mass of skeleton (including bone, red and yellow marrow, cartilage, periosteum)	Mass of skeleton
Skin_mass		Mass of skin
Small_intestine_mass		Mass of small intestine
Spleen_mass		Mass of spleen
Stomach_mass		Mass of stomach
Other_mass	Mass of GI tract contents (1.4% of body weight) and tissues not otherwise enumerated (3.3% of body weight)	Mass of other
org_mass_sum	Sum of the above tissue masses. A check to ensure this is less than body weight	Sum of tissue masses
Adipose_mass	Mass of adipose tissue. Assigned as weight - (org_mass_sum + blood_mass + brain_mass + gonads_mass + heart_mass + kidneys_mass + large_intestine_mass + liver_mass + lung_mass + muscle_mass + pancreas_mass + skeleton_mass + skin_mass + small_intestine_mass + spleen_mass + stomach_mass + other_mass)	Mass of adipose

Tissue flows

Name	Definition	Units
Adipose_flow	Blood flow to adipose tissue	ml/min
Brain_flow	Blood flow to brain tissue	ml/min
CO	Cardiac output	ml/min
Gonads_flow	Blood flow to gonads tissue	ml/min
Heart_flow	Blood flow to heart tissue	ml/min
Kidneys_flow	Blood flow to kidneys tissue (not for glomerular filtration)	ml/min
Large_intestine_flow	Blood flow to large intestine tissue	ml/min
Liver_flow	Blood flow to liver tissue	ml/min
Lung_flow	Blood flow to lung tissue	ml/min
Muscle_flow	Blood flow to skeletal muscle tissue	ml/min
Pancreas_flow	Blood flow to pancreas tissue	ml/min
Skeleton_flow	Blood flow to skeleton tissue	ml/min
Skin_flow	Blood flow to skin tissue	ml/min
Small_intestine_flow	Blood flow to small intestine tissue	ml/min

Spleen_flow

Blood flow to spleen

Stomach_flow

Blood flow to stomach

org_flow_check

Sum of blood flows as a fraction of cardiac output (CO). A check to make sure this is less than 1

Adjusted variables

Name	
weight_adj	
BSA_adj	
million.cells.per.gliver	
gfr_est	Glomerular filtration rate (GFR) estimated using either the CKD-EPI equation or the Cockcroft-Gault equation
bmi_adj	
weight_class	Weight category based on bmi_adj: "Underweight" (BMI < 18.5), "Normal" (18.5 <= BMI < 25), "Overweight" (25 <= BMI < 30), "Obese" (BMI >= 30)
gfr_class	Kidney function category based on GFR: "Normal" (GFR >= 60 mL/min/1.73 m^2), "Mildly decreased" (30 < GFR < 60), "Moderately decreased" (15 < GFR <= 30), "Severely decreased" (GFR <= 15)

Examples

```
#Simply generate a virtual population of 100 individuals,
#using the direct-resampling method
set.seed(42)
httkpop_generate(method='direct resampling', nsamp=100)
#Generate a population using the virtual-individuals method,
#includeing 80 females and 20 males,
#includeing only ages 20-65,
#includeing only Mexican American and
#Non-Hispanic Black individuals,
#includeing only non-obese individuals
httkpop_generate(method = 'virtual individuals',
gendernum=list(Female=80,
Male=20),
agelim_years=c(20,65),
reths=c('Mexican American',
'Non-Hispanic Black'),
weight_category=c('Underweight',
'Normal',
'Overweight'))
```

httkpop_mc

*httk-pop: Correlated human physiological parameter Monte Carlo***Description**

This is the core function for httk-pop correlated human physiological variability simulation as described by Ring et al. (2017) ([doi:10.1016/j.envint.2017.06.004](https://doi.org/10.1016/j.envint.2017.06.004)). This function takes the data table of population biometrics (one individual per row) generated by [httkpop_generate](#), and converts it to the corresponding table of HTTK model parameters for a specified HTTK model.

Usage

```
httkpop_mc(model, samples = 1000, httkpop.dt = NULL, ...)
```

Arguments

<code>model</code>	One of the HTTK models: "1compartment", "3compartmentss", "3compartment", or "pbtk".
<code>samples</code>	The number of Monte Carlo samples to use (can often think of these as separate individuals)
<code>httkpop.dt</code>	A data table generated by httkpop_generate . This defaults to NULL, in which case httkpop_generate is called to generate this table.
<code>...</code>	Additional arguments passed on to httkpop_generate .

Details

The Monte Carlo methods used here were recently updated and described by Breen et al. (submitted).

Value

A data.table with a row for each individual in the sample and a column for each parameter in the model.

Examples

```
set.seed(42)
indiv_examp <- httkpop_generate(method="d", nsamp=100)
httk_param <- httkpop_mc(httkpop.dt=indiv_examp,
  model="1compartment")
```

httkpop_virtual_indiv *Generate a virtual population by the virtual individuals method.*

Description

Generate a virtual population by the virtual individuals method.

Usage

```
httkpop_virtual_indiv(
  nsamp = NULL,
  gendernum = NULL,
  agelim_years = NULL,
  agelim_months = NULL,
  weight_category = c("Underweight", "Normal", "Overweight", "Obese"),
  gfr_category = c("Normal", "Kidney Disease", "Kidney Failure"),
  reths = c("Mexican American", "Other Hispanic", "Non-Hispanic White",
            "Non-Hispanic Black", "Other"),
  gfr_resid_var = TRUE,
  ckd_epi_race_coeff = FALSE,
  nhanes_mec_svy
)
```

Arguments

nsamp	The desired number of individuals in the virtual population. nsamp need not be provided if gendernum is provided.
gendernum	Optional: A named list giving the numbers of male and female individuals to include in the population, e.g. <code>list(Male=100,Female=100)</code> . Default is NULL, meaning both males and females are included, in their proportions in the NHANES data. If both nsamp and gendernum are provided, they must agree (i.e., nsamp must be the sum of gendernum).
agelim_years	Optional: A two-element numeric vector giving the minimum and maximum ages (in years) to include in the population. Default is <code>c(0,79)</code> . If agelim_years is provided and agelim_months is not, agelim_years will override the default value of agelim_months.
agelim_months	Optional: A two-element numeric vector giving the minimum and maximum ages (in months) to include in the population. Default is <code>c(0, 959)</code> , equivalent to the default agelim_years. If agelim_months is provided and agelim_years is not, agelim_months will override the default values of agelim_years.
weight_category	Optional: The weight categories to include in the population. Default is <code>c('Underweight', 'Normal', 'Overweight', 'Obese')</code> . User-supplied vector must contain one or more of these strings.
gfr_category	The kidney function categories to include in the population. Default is <code>c('Normal', 'Kidney Disease', 'Kidney Failure')</code> to include all kidney function levels.
reths	Optional: a character vector giving the races/ethnicities to include in the population. Default is <code>c('Mexican American', 'Other Hispanic', 'Non-Hispanic White', 'Non-Hispanic Black', 'Other')</code> , to include all races and ethnicities

in their proportions in the NHANES data. User-supplied vector must contain one or more of these strings.

`gfr_resid_var` Logical value indicating whether or not to include residual variability when generating GFR values. (Default is TRUE.)

`ckd_epi_race_coeff` Logical value indicating whether or not to use the "race coefficient" from the CKD-EPI equation when estimating GFR values. (Default is FALSE.)

`nhanes_mec_svy` `surveydesign` object created from `mecdt` using `svydesign` (this is done in `htkpop_generate`, which calls this function)

Value

A `data.table` where each row represents an individual, and each column represents a demographic, anthropometric, or physiological parameter.

hw_H	<i>KDE bandwidth for residual variability in height/weight</i>
------	--

Description

Bandwidths used for a two-dimensional kernel density estimation of the joint distribution of residual errors around smoothing spline fits of height vs. age and weight vs. age for NHANES respondents in each of ten combinations of sex and race/ethnicity categories.

Usage

hw_H

Format

A named list with 10 elements, each a matrix with 2 rows and 2 columns. Each list element corresponds to, and is named for, one combination of NHANES sex categories (Male and Female) and NHANES race/ethnicity categories (Mexican American, Other Hispanic, Non-Hispanic White, Non-Hispanic Black, and Other).

Details

Each matrix is a variance-covariance matrix for a two-dimensional normal distribution: this is the bandwidth to be used for a two-dimensional kernel density estimation (KDE) (using a two-dimensional normal kernel) of the joint distribution of residual errors around smoothing spline fits of height vs. age and weight vs. age for NHANES respondents in the specified sex and race/ethnicity category. Optimal bandwidths were pre-calculated by doing the smoothing spline fits, getting the residuals, then calling `kde` on the residuals (which calls `Hpi` to compute the plug-in bandwidth).

Used by HHTK-Pop only in "virtual individuals" mode (i.e. `httkpop_generate` with `method = "v"`), in `gen_height_weight`.

in.list

Convenience Boolean (yes/no) functions to identify chemical membership in several key lists.

Description

These functions allow easy identification of whether or not a chemical CAS is included in various research projects. While it is our intent to keep these lists up-to-date, the information here is only for convenience and should not be considered to be definitive.

Usage

```
in.list(chem.cas = NULL, which.list = "ToxCast")
```

Arguments

`chem.cas` The Chemical Abstracts Service Registry Number (CAS-RN) corresponding to the chemical of interest.

`which.list` A character string that can take the following values: "ToxCast", "Tox21", "ExpoCast", "NHANES", "NHANES.serum.parent", "NHANES.serum.analyte", "NHANES.blood.parent", "NHANES.urine.parent", "NHANES.urine.analyte"

Details

Tox21: Toxicology in the 21st Century (Tox21) is a U.S. federal High Throughput Screening (HTS) collaboration among EPA, NIH, including National Center for Advancing Translational Sciences and the National Toxicology Program at the National Institute of Environmental Health Sciences, and the Food and Drug Administration. (Bucher et al., 2008)

ToxCast: The Toxicity Forecaster (ToxCast) is a HTS screening project led by the U.S. EPA to perform additional testing of a subset of Tox21 chemicals. (Judson et al. 2010)

ExpoCast: ExpoCast (Exposure Forecaster) is an U.S. EPA research project to generate tentative exposure estimates (e.g., mg/kg BW/day) for thousands of chemicals that have little other information using models and informatics. (Wambaugh et al. 2014)

NHANES: The U.S. Centers for Disease Control (CDC) National Health and Nutrition Examination Survey (NHANES) is an on-going survey to characterize the health and biometrics (e.g., weight, height) of the U.S. population. One set of measurements includes the quantification of xenobiotic chemicals in various samples (blood, serum, urine) of the thousands of surveyed individuals. (CDC, 2014)

Value

logical A Boolean (1/0) value that is TRUE if the chemical is in the list.

  }

```

 invitro_mc

Monte Carlo for in vitro toxicokinetic parameters including uncertainty and variability.

Description

Given a CAS in the HTTK data set, a virtual population from HTTK-Pop, some user specifications on the assumed distributions of Funbound.plasma and Clint, draw "individual" values of Funbound.plasma and Clint from those distributions. The methodology for this function was developed and described by Wambaugh et al. (2019) ([doi:10.1093/toxsci/kfz205](https://doi.org/10.1093/toxsci/kfz205)).

Usage

```

invitro_mc(
  parameters.dt = NULL,
  samples,
  fup.meas.mc = TRUE,
  fup.pop.mc = TRUE,
  clint.meas.mc = TRUE,
  clint.pop.mc = TRUE,
  fup.meas.cv = 0.4,
  clint.meas.cv = 0.3,
  fup.pop.cv = 0.3,
  clint.pop.cv = 0.3,
  poormetab = TRUE,
  fup.lod = 0.01,
  fup.censored.dist = FALSE,
  adjusted.Funbound.plasma = TRUE,
  adjusted.Clint = TRUE,
  clint.pvalue.threshold = 0.05,
  minimum.Funbound.plasma = 1e-04
)

```

Arguments

parameters.dt	A data table of physiological and chemical-specific parameters
samples	The number of samples to draw.
fup.meas.mc	Logical – should we perform measurement (uncertainty) Monte Carlo for Funbound.plasma values (Default TRUE). If FALSE, the user may choose to provide columns for "unadjusted.Funbound.plasma" or "fup.mean" from their own methods.
fup.pop.mc	Logical – should we perform population (variability) Monte Carlo for Funbound.plasma values (Default TRUE)
clint.meas.mc	Logical – should we perform measurement (uncertainty) Monte Carlo for Clint values (Default TRUE)

clint.pop.mc	Logical – should we perform population (variability) Monte Carlo for Clint values (Default TRUE)
fup.meas.cv	Coefficient of variation of distribution of measured Funbound.plasma values.
clint.meas.cv	Coefficient of variation of distribution of measured Clint values.
fup.pop.cv	Coefficient of variation of distribution of population Funbound.plasma values.
clint.pop.cv	Coefficient of variation of distribution of population Clint values.
poormetab	Logical. Whether to include poor metabolizers in the Clint distribution or not.
fup.lod	The average limit of detection for Funbound.plasma, below which distribution will be censored if fup.censored.dist is TRUE. Default 0.01.
fup.censored.dist	Logical. Whether to draw Funbound.plasma from a censored distribution or not.
adjusted.Funbound.plasma	Uses Pearce et al. (2017) lipid binding adjustment for Funbound.plasma when set to TRUE (Default).
adjusted.Clint	Uses Kilford et al. (2008) hepatocyte incubation binding adjustment for Clint when set to TRUE (Default).
clint.pvalue.threshold	Hepatic clearance for chemicals where the in vitro clearance assay result has a p-values greater than the threshold are set to zero.
minimum.Funbound.plasma	Monte Carlo draws less than this value are set equal to this value (default is 0.0001 – half the lowest measured Fup in our dataset).
parameters	A list of chemical-specific model parameters containing at least Funbound.plasma, Clint, and Fhep.assay.correction.

Details

The Monte Carlo methods used here were recently updated and described by Breen et al. (submitted).

Value

A data.table with three columns: Funbound.plasma and Clint, containing the sampled values, and Fhep.assay.correction, containing the value for fraction unbound in hepatocyte assay.

# Convert to data.table with one row per sample:
parameters.dt <- monte_carlo(chem.props,samples=100)
# Use httk-pop to generate a population:
pop <- httkpop_generate(method='direct resampling', nsamp=100)
# Overwrite parameters specified by httk-pop:
parameters.dt[,names(pop):=pop]
# Vary in vitro parameters:
parameters.dt <- invitro_mc(parameters.dt,samples=100)
```

is.httk

Convenience Boolean (yes/no) function to identify chemical membership and treatment within the httk project.

Description

Allows easy identification of whether or not a chemical CAS is included in various aspects of the httk research project (by model type and species of interest). While it is our intent to keep these lists up-to-date, the information here is only for convenience and should not be considered definitive.

Usage

```
is.httk(chem.cas, species = "Human", model = "3compartmentss")
```

Arguments

chem.cas	The Chemical Abstracts Service Registry Number (CAS-RN) corresponding to the chemical of interest.
species	Species desired (either "Rat", "Rabbit", "Dog", "Mouse", or default "Human").
model	Model used in calculation, 'pbt' for the multiple compartment model, '1compartment' for the one compartment model, '3compartment' for three compartment model, '3compartmentss' for the three compartment model without partition coefficients, or 'schmitt' for chemicals with logP and fraction unbound (used in predict_partitioning_schmitt).

is_in_inclusive	<i>Checks whether a value, or all values in a vector, is within inclusive limits</i>
-----------------	--

Description

Checks whether a value, or all values in a vector, is within inclusive limits

Usage

```
is_in_inclusive(x, lims)
```

Arguments

x	A numeric value, or vector of values.
lims	A two-element vector of (min, max) values for the inclusive limits. If x is a vector, lims may also be a two-column matrix with nrow=length(x) where the first column is lower limits and the second column is upper limits. If x is a vector and lims is a two-element vector, then each element of x will be checked against the same limits. If x is a vector and lims is a matrix, then each element of x will be checked against the limits given by the corresponding row of lims.

Value

A logical vector the same length as x, indicating whether each element of x is within the inclusive limits given by lims.

kapraun2019*Kapraun et al. 2019 data*

Description

A list object containing time-varying parameters for the human maternal-fetal HTTK model. List elements contain scalar coefficients for the polynomial, logistic, Gompertz, and other functions of time describing blood flow rates, tissue volumes, hematocrits, and other anatomical/physiological quantities that change in the human mother and her fetus during pregnancy and gestation.

Usage

kapraun2019

Format

list

kidney_mass_children	<i>Predict kidney mass for children</i>
----------------------	---

Description

For individuals under age 18, predict kidney mass from weight, height, and gender. using equations from Ogiu et al. 1997

Usage

```
kidney_mass_children(weight, height, gender)
```

Arguments

weight	Vector of weights in kg.
height	Vector of heights in cm.
gender	Vector of genders (either 'Male' or 'Female').

Value

A vector of kidney masses in kg.

Author(s)

Caroline Ring

References

Ogiu, Nobuko, et al. "A statistical analysis of the internal organ weights of normal Japanese people." *Health physics* 72.3 (1997): 368-383.

liver_mass_children	<i>Predict liver mass for children</i>
---------------------	--

Description

For individuals under 18, predict the liver mass from height, weight, and gender, using equations from Ogiu et al. 1997

Usage

```
liver_mass_children(height, weight, gender)
```

Arguments

height	Vector of heights in cm.
weight	Vector of weights in kg.
gender	Vector of genders (either 'Male' or 'Female').

Value

A vector of liver masses in kg.

load_dawson2021	<i>Load data from Dawson et al. 2021.</i>
-----------------	---

Description

This function returns an updated version of chem.physical_and_invitro.data that includes data predicted with Random Forest QSAR models developed and presented in Dawson et al. 2021, included in dawson2021.

Usage

```
load_dawson2021(overwrite = FALSE, exclude_oad = TRUE, target.env = .GlobalEnv)
```

Arguments

<code>overwrite</code>	Only matters if <code>load.image=FALSE</code> . If <code>overwrite=TRUE</code> then existing data in <code>chem.physical_and_invitro.data</code> will be replaced by any data/predictions in Dawson et al. (2021) that is for the same chemical and property. If <code>overwrite=FALSE</code> (DEFAULT) then new data for the same chemical and property are ignored. Fun-bound.plasma values of 0 (below limit of detection) are overwritten either way.
<code>exclude_oad</code>	Include the chemicals only within the applicability domain. If <code>exlude_oad=TRUE</code> (DEFAULT) chemicals outside the applicability domain do not have their predicted values loaded.
<code>target.env</code>	The environment where the new <code>chem.physical_and_invitro.data</code> is loaded. Defaults to global environment.

Value

<code>data.frame</code>	An updated version of <code>chem.physical_and_invitro.data</code> .
-------------------------	---

Author(s)

Sarah E. Davidson

Examples

```
## Not run:
chem.physical_and_invitro.data <- load_dawson2021()
chem.physical_and_invitro.data <- load_dawson2021(overwrite=TRUE)

## End(Not run)
```

<code>load_pradeep2020</code>	<i>Load data from Pradeep et al. 2020.</i>
-------------------------------	--

Description

This function returns an updated version of `chem.physical_and_invitro.data` that includes data predicted with Support Vector Machine and Random Forest models developed and presented in Pradeep et al. 2020, included in `pradeep2020`.

Usage

```
load_pradeep2020(overwrite = FALSE, target.env = .GlobalEnv)
```

Arguments

overwrite	Only matters if load.image=FALSE. If overwrite=TRUE then existing data in chem.physical_and_invitro.data will be replaced by any data/predictions in Pradeep et al. (2020) that is for the same chemical and property. If overwrite=FALSE (DEFAULT) then new data for the same chemical and property are ignored. Funbound.plasma values of 0 (below limit of detection) are overwritten either way.
target.env	The environment where the new chem.physical_and_invitro.data is loaded. Defaults to global environment.

Value

data.frame	An updated version of chem.physical_and_invitro.data.

Examples

```
## Not run:
chem.physical_and_invitro.data <- load_pradeep2020()
chem.physical_and_invitro.data <- load_pradeep2020(overwrite=TRUE)

## End(Not run)
```

load_sipes2017	<i>Load data from Sipes et al 2017.</i>
----------------	---

Description

This function returns an updated version of chem.physical_and_invitro.data that includes data predicted with Simulations Plus' ADMET predictor that was used in Sipes et al. 2017, included in admet.data.

Usage

```
load_sipes2017(overwrite = FALSE, target.env = .GlobalEnv)
```

Arguments

<code>overwrite</code>	Only matters if <code>load.image=FALSE</code> . If <code>overwrite=TRUE</code> then existing data in <code>chem.physical_and_invitro.data</code> will be replaced by any data/predictions in Sipes et al. (2017) that is for the same chemical and property. If <code>overwrite=FALSE</code> (DEFAULT) then new data for the same chemical and property are ignored. Funbound.plasma values of 0 (below limit of detection) are overwritten either way.
<code>target.env</code>	The environment where the new <code>chem.physical_and_invitro.data</code> is loaded. Defaults to global environment.

Value

<code>data.frame</code>	An updated version of <code>chem.physical_and_invitro.data</code> .
-------------------------	---

Robert Pearce and John Wambaugh

References

Sipes, Nisha S., et al. "An intuitive approach for predicting potential human health risk with the Tox21 10k library." *Environmental Science & Technology* 51.18 (2017): 10786-10796.

Examples

```
num.chems <- length(get_cheminfo())
load_sipes2017()

#We should have the ADMet Predicted chemicals from Sipes et al. (2017),
#this one is a good test since the logP is nearly 10
calc_css(chem.cas="26040-51-7")

#Let's see how many chemicals we have now with the Sipes (2017) data loaded:
length(get_cheminfo())

#Now let us reset
reset_httk()

# We should be back to our original number:
num.chems == length(get_cheminfo())
```

lump_tissues

Lump tissue parameters

Description

This function takes the parameters from `predict_partitioning_schmitt` and lumps the partition coefficients along with the volumes and flows based on the given tissue list. It is useful in Monte Carlo simulation of individual partition coefficients when calculating the rest of body partition coefficient.

Usage

```
lump_tissues(
  Ktissue2pu.in,
  parameters = NULL,
  tissuelist = NULL,
  species = "Human",
  tissue.vols = NULL,
  tissue.flows = NULL,
  model = "pbt",
  suppress.messages = FALSE
)
```

Arguments

<code>Ktissue2pu.in</code>	List of partition coefficients from <code>predict_partitioning_schmitt</code> .
<code>parameters</code>	A list of physiological parameters including flows and volumes for tissues in <code>tissuelist</code>
<code>tissuelist</code>	Manually specifies compartment names and tissues, which override the standard compartment names and tissues that are usually specified in a model's associated <code>modelinfo</code> file. Remaining tissues in the model's associated <code>alltissues</code> listing are lumped in the rest of the body.
<code>species</code>	Species desired (either "Rat", "Rabbit", "Dog", "Mouse", or default "Human").
<code>tissue.vols</code>	A list of volumes for tissues in <code>tissuelist</code>
<code>tissue.flows</code>	A list of flows for tissues in <code>tissuelist</code>
<code>model</code>	Specify which model (and therefore which tissues) are being considered
<code>suppress.messages</code>	Whether or not the output message is suppressed.

Details

This function returns the flows, volumes, and partition coefficients for the lumped tissues specified in tissue list `Ktissue2plasma` – tissue to free plasma concentration partition coefficients for every tissue specified by Schmitt (2008) (the `tissue.data` table) `tissuelist` – a list of character vectors, the name of each entry in the list is its own compartment. The tissues in the `alltissues` vector are the Schmitt (2008) tissues that are to be considered in the lumping process. The `tissuelist` can also be manually specified for alternate lumping schemes: for example, `tissuelist<-list(Rapid=c("Brain","Kidney"))` specifies the `flow.col` and `vol.col` in the `tissuedata.table`.

Value

<code>Krbc2pu</code>	Ratio of concentration of chemical in red blood cells to unbound concentration in plasma.
<code>Krest2pu</code>	Ratio of concentration of chemical in rest of body tissue to unbound concentration in plasma.
<code>Vrestc</code>	Volume of the rest of the body per kg body weight, L/kg BW.
<code>Vliverc</code>	Volume of the liver per kg body weight, L/kg BW.
<code>Qtotall.liverf</code>	Fraction of cardiac output flowing to the gut and liver, i.e. out of the liver.
<code>Qgutf</code>	Fraction of cardiac output flowing to the gut.
<code>Qkidneyf</code>	Fraction of cardiac output flowing to the kidneys.

Examples

```
pcs <- predict_partitioning_schmitt(chem.name='bisphenola')
tissuelist <- list(liver=c("liver"),kidney=c("kidney"),lung=c("lung"),gut=c("gut"),
muscle.bone=c('muscle','bone'))
lump_tissues(pcs,tissuelist=tissuelist)
```

lung_mass_children	<i>Predict lung mass for children</i>
--------------------	---------------------------------------

Description

For individuals under 18, predict the liver mass from height, weight, and gender, using equations from Ogiu et al. 1997

Usage

```
lung_mass_children(height, weight, gender)
```

Arguments

height	Vector of heights in cm.
weight	Vector of weights in kg.
gender	Vector of genders (either 'Male' or 'Female').

Value

A vector of lung masses in kg.

mcnally_dt*Reference tissue masses and flows from tables in McNally et al. 2014.*

Description

Reference tissue masses, flows, and residual variance distributions from Tables 1, 4, and 5 of McNally et al. 2014.

Usage

mcnally_dt

Format

A data.table with variables:

tissue Body tissue

gender Gender: Male or Female

mass_ref Reference mass in kg, from Reference Man

mass_cv Coefficient of variation for mass

mass_dist Distribution for mass: Normal or Log-normal

flow_ref Reference flow in L/h, from Reference Man

flow_cv Coefficient of variation for flow (all normally distributed)

height_ref Reference heights (by gender)

CO_ref Reference cardiac output by gender

flow_frac Fraction of CO flowing to each tissue: flow_ref/CO_ref

mecdt

*Pre-processed NHANES data.***Description**

NHANES data on demographics, anthropometrics, and some laboratory measures, cleaned and combined into a single data set.

Usage

mecdt

Format

A data.table with 23620 rows and 12 variables.

seqn NHANES unique identifier for individual respondents.

sddsrvy NHANES two-year cycle: one of "NHANES 2013-2014", "NHANES 2015-2016", "NHANES 2017-2018".

riagendr Gender: "Male" or "Female"

ridreth1 Race/ethnicity category: one of "Mexican American", "Non-Hispanic White", "Non-Hispanic Black", "Other", "Other Hispanic".

ridexagm Age in months at the time of examination (if not recorded by NHANES, it was imputed based on age at the time of screening)

ridexagy Age in years at the time of examination (if not recorded by NHANES, it was imputed based on age at the time of screening)

bmxbwt Weight in kg

lbbxscr Serum creatinine, mg/dL

lbbxhct Hematocrit, percent by volume of blood composed of red blood cells

wtmec6yr 6-year sample weights for combining 3 cycles, computed by dividing 2-year sample weights by 3.

bmxbhtlenavg Average of height and recumbent length if both were measured; if only one was measured, takes value of the one that was measured.

weight_class One of Underweight, Normal, Overweight, or Obese. Assigned using methods in [get_weight_class](#).

`monte_carlo`*Monte Carlo for toxicokinetic model parameters*

Description

This function performs basic, uncorrelated Monte Carlo to simulate uncertainty and/or variability for parameters of toxicokinetic models. Parameters can be varied according to either a normal distribution that is truncated at zero (using argument `cv.params`) or from a normal distribution that is censored for values less than the limit of detection (`censored.params`). Coefficient of variation (`cv`) and limit of of detectin can be specified separately for each parameter.

Usage

```
monte_carlo(  
  parameters,  
  cv.params = NULL,  
  censored.params = NULL,  
  samples = 1000  
)
```

Arguments

parameters	These parameters that are also listed in either <code>cv.params</code> or <code>censored.params</code> are sampled using Monte Carlo.
cv.params	The parameters listed in <code>cv.params</code> are sampled from a normal distribution that is truncated at zero. This argument should be a list of coefficients of variation (<code>cv</code>) for the normal distribution. Each entry in the list is named for a parameter in "parameters". New values are sampled with mean equal to the value in "parameters" and standard deviation equal to the mean times the <code>cv</code> .
censored.params	The parameters listed in <code>censored.params</code> are sampled from a normal distribution that is censored for values less than the limit of detection (specified separately for each parameter). This argument should be a list of sub-lists. Each sublist is named for a parameter in "params" and contains two elements: "cv" (coefficient of variation) and "LOD" (limit of detection), below which parameter values are censored. New values are sampled with mean equal to the value in "params" and standard deviation equal to the mean times the <code>cv</code> . Censored values are sampled on a uniform distribution between 0 and the limit of detection.
samples	This argument is the number of samples to be generated for calculating quantiles.

Value

A `data.table` with a row for each individual in the sample and a column for each parameter in the model.

Author(s)

John Wambaugh

References

Pearce, Robert G., et al. "Httk: R package for high-throughput toxicokinetics." *Journal of statistical software* 79.4 (2017): 1.

Examples

```
#Example based on Pearce et al. (2017):

# Set up means:
params <- parameterize_pbt(chem.name="zoxamide")
# Nothing changes:
monte_carlo(params)

vary.params <- NULL
for (this.param in names(params)[!(names(params) %in%
  c("Funbound.plasma", "pKa_Donor", "pKa_Accept" )) &
  !is.na(as.numeric(params))]) vary.params[this.param] <- 0.2
# Most everything varies with CV of 0.2:
monte_carlo(
  parameters=params,
  cv.params = vary.params)

censored.params <- list(Funbound.plasma = list(cv = 0.2, lod = 0.01))
# Fup is censored below 0.01:
monte_carlo(
```

```
parameters=params,
cv.params = vary.params,
censored.params = censored.params)
```

Obach2008

*Published Pharmacokinetic Parameters from Obach et al. 2008***Description**

This data set is used in Vignette 4 for steady state concentration.

Usage

parameterize_1comp

Parameters for a one compartment (empirical) toxicokinetic model

Description

This function initializes the parameters needed in the function solve_1comp. Volume of distribution is estimated by using a modified Schmitt (2008) method to predict tissue partition coefficients (Pearce et al., 2017) and then lumping the compartments weighted by tissue volume:

Usage

```
parameterize_1comp(
  chem.cas = NULL,
  chem.name = NULL,
  dtxsid = NULL,
  species = "Human",
  default.to.human = FALSE,
  adjusted.Funbound.plasma = TRUE,
  adjusted.Clint = TRUE,
  regression = TRUE,
  restrictive.clearance = TRUE,
  well.stirred.correction = TRUE,
  suppress.messages = FALSE,
  clint.pvalue.threshold = 0.05,
  minimum.Funbound.plasma = 1e-04
)
```

Arguments

chem.cas	Chemical Abstract Services Registry Number (CAS-RN) – the chemical must be identified by either CAS, name, or DTXISD
chem.name	Chemical name (spaces and capitalization ignored) – the chemical must be identified by either CAS, name, or DTXISD
dtxsid	EPA's DSSTox Structure ID (https://comptox.epa.gov/dashboard) – the chemical must be identified by either CAS, name, or DTXISDs
species	Species desired (either "Rat", "Rabbit", "Dog", "Mouse", or default "Human").
default.to.human	Substitutes missing rat values with human values if true.
adjusted.Funbound.plasma	Uses Pearce et al. (2017) lipid binding adjustment for Funbound.plasma (which impacts volume of distribution) when set to TRUE (Default).
adjusted.Clint	Uses Kilford et al. (2008) hepatocyte incubation binding adjustment for Clint when set to TRUE (Default).
regression	Whether or not to use the regressions in calculating partition coefficients in volume of distribution calculation.
restrictive.clearance	In calculating elimination rate and hepatic bioavailability, protein binding is not taken into account (set to 1) in liver clearance if FALSE.
well.stirred.correction	Uses correction in calculation of hepatic clearance for well-stirred model if TRUE. This assumes clearance relative to amount unbound in whole blood instead of plasma, but converted to use with plasma concentration.
suppress.messages	Whether or not to suppress messages.
clint.pvalue.threshold	Hepatic clearance for chemicals where the in vitro clearance assay result has a p-value greater than the threshold are set to zero.
minimum.Funbound.plasma	Monte Carlo draws less than this value are set equal to this value (default is 0.0001 – half the lowest measured Fup in our dataset).

Details

$$V_{d,steady-state} = \sum_{i \in tissues} K_i V_i + V_{plasma}$$

where K_i is the tissue:unbound plasma concentration partition coefficient for tissue i .

Value

Vdist	Volume of distribution, units of L/kg BW.
Fgutabs	Fraction of the oral dose absorbed, i.e. the fraction of the dose that enters the gutlumen.
Fhep.assay.correction	The fraction of chemical unbound in hepatocyte assay using the method of Kilford et al. (2008)
kelim	Elimination rate, units of 1/h.
hematocrit	Percent volume of red blood cells in the blood.
kgutabs	Rate chemical is absorbed, 1/h.
million.cells.per.gliver	Millions cells per gram of liver tissue.
MW	Molecular Weight, g/mol.
Rblood2plasma	The ratio of the concentration of the chemical in the blood to the concentration in the plasma. Not used in calculations but included for the conversion of plasma outputs.
hepatic.bioavailability	Fraction of dose remaining after first pass clearance, calculated from the corrected well-stirred model.
BW	Body Weight, kg.

Examples

```
parameters <- parameterize_1comp(chem.name='Bisphenol-A',species='Rat')
parameters <- parameterize_1comp(chem.cas='80-05-7',
                                restrictive.clearance=FALSE,
                                species='rabbit',
                                default.to.human=TRUE)
out <- solve_1comp(parameters=parameters)
```

parameterize_3comp	<i>Parameters for a three-compartment toxicokinetic model (dynamic)</i>
--------------------	---

Description

This function generates the chemical- and species-specific parameters needed for model '3compartment', for example [solve_3comp](#). A call is made to [parameterize_pbtok](#) to use Schmitt (2008)'s method as modified by Pearce et al. (2017) to predict partition coefficients based on descriptions in [tissue.data](#). Organ volumes and flows are retrieved from table [physiology.data](#).

Usage

```
parameterize_3comp(  
  chem.cas = NULL,  
  chem.name = NULL,  
  dtxsid = NULL,  
  species = "Human",  
  default.to.human = FALSE,  
  force.human.clint.fup = FALSE,  
  clint.pvalue.threshold = 0.05,  
  adjusted.Funbound.plasma = TRUE,  
  adjusted.Clint = TRUE,  
  regression = TRUE,  
  suppress.messages = FALSE,  
  restrictive.clearance = TRUE,  
  minimum.Funbound.plasma = 1e-04  
)
```

Arguments

chem.cas	Chemical Abstract Services Registry Number (CAS-RN) – the chemical must be identified by either CAS, name, or DTXISD
chem.name	Chemical name (spaces and capitalization ignored) – the chemical must be identified by either CAS, name, or DTXISD
dtxsid	EPA's 'DSSTox Structure ID (https://comptox.epa.gov/dashboard) – the chemical must be identified by either CAS, name, or DTXSIDs
species	Species desired (either "Rat", "Rabbit", "Dog", "Mouse", or default "Human").
default.to.human	Substitutes missing animal values with human values if true.
force.human.clint.fup	Forces use of human values for hepatic intrinsic clearance and fraction of unbound plasma if true.
clint.pvalue.threshold	Hepatic clearances with clearance assays having p-values greater than the threshold are set to zero.
adjusted.Funbound.plasma	Uses Pearce et al. (2017) lipid binding adjustment for Funbound.plasma (which impacts partition coefficients) when set to TRUE (Default).

adjusted.Clint	Uses Kilford et al. (2008) hepatocyte incubation binding adjustment for Clint when set to TRUE (Default).
regression	Whether or not to use the regressions in calculating partition coefficients.
suppress.messages	Whether or not the output message is suppressed.
restrictive.clearance	In calculating hepatic.bioavailability, protein binding is not taken into account (set to 1) in liver clearance if FALSE.
minimum.Funbound.plasma	Monte Carlo draws less than this value are set equal to this value (default is 0.0001 – half the lowest measured Fup in our dataset).

Value

BW	Body Weight, kg.
Clmetabolismc	Hepatic Clearance, L/h/kg BW.
Fgutabs	Fraction of the oral dose absorbed, i.e. the fraction of the dose that enters the gutlumen.
Funbound.plasma	Fraction of plasma that is not bound.
Fhep.assay.correction	The fraction of chemical unbound in hepatocyte assay using the method of Kilford et al. (2008)
hematocrit	Percent volume of red blood cells in the blood.
Kgut2pu	Ratio of concentration of chemical in gut tissue to unbound concentration in plasma.
Kliver2pu	Ratio of concentration of chemical in liver tissue to unbound concentration in plasma.
Krbc2pu	Ratio of concentration of chemical in red blood cells to unbound concentration in plasma.
Krest2pu	Ratio of concentration of chemical in rest of body tissue to unbound concentration in plasma.
million.cells.per.gliver	Millions cells per gram of liver tissue.
MW	Molecular Weight, g/mol.
Qcardiac	Cardiac Output, L/h/kg BW ^{3/4} .
Qgfr	Glomerular Filtration Rate, L/h/kg BW ^{3/4} , volume of fluid filtered from kidney and excreted.
Qgut	Fraction of cardiac output flowing to the gut.
Qliver	Fraction of cardiac output flowing to the liver.
Rblood2plasma	The ratio of the concentration of the chemical in the blood to the concentration in the plasma.
Vgut	Volume of the gut per kg body weight, L/kg BW.
Vliver	Volume of the liver per kg body weight, L/kg BW.
Vrest	Volume of the rest of the body per kg body weight, L/kg BW.

Examples

```
parameters <- parameterize_3comp(chem.name='Bisphenol-A',species='Rat')
parameters <- parameterize_3comp(chem.cas='80-05-7',
                                species='rabbit',default.to.human=TRUE)
out <- solve_3comp(parameters=parameters,plots=TRUE)
```

parameterize_fetal_pbt

Parameterize_fetal_PBT

Description

This function initializes the parameters needed in the functions solve_fetal_pbt by calling solve_pbt and adding additional parameters.

Usage

```
parameterize_fetal_pbt(
  chem.cas = NULL,
  chem.name = NULL,
  dtxsid = NULL,
  species = "Human",
  fetal_fup_adjustment = TRUE,
  return.kapraun2019 = TRUE,
  suppress.messages = FALSE,
  ...
)
```

Arguments

chem.cas	Either the chemical name or the CAS number must be specified.
chem.name	Either the chemical name or the CAS number must be specified.
dtxsid	EPA's DSSTox Structure ID (http://comptox.epa.gov/dashboard) the chemical must be identified by either CAS, name, or DTXSIDs
species	Species desired (either "Rat", "Rabbit", "Dog", "Mouse", or default "Human"). Currently only a narrow human model is supported.
fetal_fup_adjustment	Logical indicator of whether to use an adjusted estimate for fetal fup based on the fetal:maternal plasma protein binding ratios presented in McNamara and Alcorn's 2002 study "Protein Binding Predictions in Infants." Defaults to TRUE.
return.kapraun2019	If TRUE (default) the empirical parameters for the Kapraun et al. (2019) maternal-fetal growth parameters are provided.
suppress.messages	Whether or not the output message is suppressed.
...	Arguments passed to parameterize_pbt.

Value

pre_pregnant_BW	Body Weight before pregnancy, kg.
Clmetabolismc	Hepatic Clearance, L/h/kg BW.
Fgutabs	Fraction of the oral dose absorbed, i.e. the fraction of the dose that enters the gutlumen.
Funbound.plasma	Fraction of plasma that is not bound.
Fhep.assay.correction	The fraction of chemical unbound in hepatocyte assay using the method of Kilford et al. (2008)
hematocrit	Percent volume of red blood cells in the blood.
Kgut2pu	Ratio of concentration of chemical in gut tissue to unbound concentration in plasma.
kgutabs	Rate that chemical enters the gut from gutlumen, 1/h.
Kkidney2pu	Ratio of concentration of chemical in kidney tissue to unbound concentration in plasma.
Kliver2pu	Ratio of concentration of chemical in liver tissue to unbound concentration in plasma.
Klung2pu	Ratio of concentration of chemical in lung tissue to unbound concentration in plasma.
Krbc2pu	Ratio of concentration of chemical in red blood cells to unbound concentration in plasma.
Krest2pu	Ratio of concentration of chemical in rest of body tissue to unbound concentration in plasma.
million.cells.per.gliver	Millions cells per gram of liver tissue.
MW	Molecular Weight, g/mol.

Qgfrc	Glomerular Filtration Rate, L/h/kg BW ^{3/4} , volume of fluid filtered from kidney and excreted.
Rblood2plasma	The ratio of the concentration of the chemical in the blood to the concentration in the plasma from available_rblood2plasma.
Vgutc	Volume of the gut per kg body weight, L/kg BW.
Vkidneyc	Volume of the kidneys per kg body weight, L/kg BW.
Vliverc	Volume of the liver per kg body weight, L/kg BW.
Vlungc	Volume of the lungs per kg body weight, L/kg BW.
Vthyroidc	Volume of the thyroid per kg body weight, L/kg BW.
Kfgut2pu	Ratio of concentration of chemical in fetal gut tissue to unbound concentration in plasma.
Kfkidney2pu	Ratio of concentration of chemical in fetal kidney tissue to unbound concentration in plasma.
Kfliver2pu	Ratio of concentration of chemical in fetal liver tissue to unbound concentration in plasma.
Kflung2pu	Ratio of concentration of chemical in fetal lung tissue to unbound concentration in plasma.
Kfrest2pu	Ratio of concentration of chemical in fetal rest of body tissue to unbound concentration in plasma.
Kfbrain2pu	Ratio of concentration of chemical in fetal brain tissue to unbound concentration in plasma.
Kthyroid2pu	Ratio of concentration of chemical in fetal thyroid tissue to unbound concentration in plasma.
Kfthyroid2pu	Ratio of concentration of chemical in fetal thyroid tissue to unbound concentration in plasma.
Kplacenta2pu	Ratio of concentration of chemical in placental tissue to unbound concentration in maternal plasma.
Kfplacenta2pu	Ratio of concentration of chemical in placental tissue to unbound concentration in fetal plasma.

parameterize_gas_pbt	<i>Parameters for a generic gas inhalation physiologically-based toxicokinetic model</i>
----------------------	--

Description

This function initializes the parameters needed for the model 'gas_pbt', for example [solve_gas_pbt](#). Chemical- and species-specific model parameters are generated. These include tissue:plasma partition coefficients via Schmitt (2008)'s method as modified by Pearce et al. (2017). Organ volumes and flows are retrieved from table [physiology.data](#)). This model was first described by Linakis et al. (2020).

Usage

```
parameterize_gas_pbt(
  chem.cas = NULL,
  chem.name = NULL,
  dtxsid = NULL,
  species = "Human",
  default.to.human = FALSE,
  tissuelist = list(liver = c("liver"), kidney = c("kidney"), lung = c("lung"), gut =
    c("gut")),
  force.human.clint.fup = FALSE,
  clint.pvalue.threshold = 0.05,
  adjusted.Funbound.plasma = TRUE,
  adjusted.Clint = TRUE,
  regression = TRUE,
  vmax = 0,
  km = 1,
  exercise = FALSE,
  fR = 12,
  VT = 0.75,
  VD = 0.15,
  suppress.messages = FALSE,
  minimum.Funbound.plasma = 1e-04,
  ...
)
```

Arguments

chem.cas	Either the chemical name or the CAS number must be specified.
chem.name	Either the chemical name or the CAS number must be specified.

dtxsid	EPA's DSSTox Structure ID (https://comptox.epa.gov/dashboard) the chemical must be identified by either CAS, name, or DTXSIDs
species	Species desired (either "Rat", "Rabbit", "Dog", "Mouse", or default "Human").
default.to.human	Substitutes missing animal values with human values if true (hepatic intrinsic clearance or fraction of unbound plasma).
tissuelist	Specifies compartment names and tissues groupings. Remaining tissues in tissue.data are lumped in the rest of the body. However, solve_pbt only works with the default parameters.
force.human.clint.fup	Forces use of human values for hepatic intrinsic clearance and fraction of unbound plasma if true.
clint.pvalue.threshold	Hepatic clearance for chemicals where the in vitro clearance assay result has a p-values greater than the threshold are set to zero.
adjusted.Funbound.plasma	Uses Pearce et al. (2017) lipid binding adjustment for Funbound.plasma (which impacts partition coefficients) when set to TRUE (Default).
adjusted.Clint	Uses Kilford et al. (2008) hepatocyte incubation binding adjustment for Clint when set to TRUE (Default).
regression	Whether or not to use the regressions in calculating partition coefficients.
vmax	Michaelis-Menten vmax value in reactions/min
km	Michaelis-Menten concentration of half-maximal reaction velocity in desired output concentration units.
exercise	Logical indicator of whether to simulate an exercise-induced heightened respiration rate
fR	Respiratory frequency (breaths/minute), used especially to adjust breathing rate in the case of exercise. This parameter, along with VT and VD (below) gives another option for calculating Q _{alv} (Alveolar ventilation) in case pulmonary ventilation rate is not known
VT	Tidal volume (L), to be modulated especially as part of simulating the state of exercise
VD	Anatomical dead space (L), to be modulated especially as part of simulating the state of exercise
suppress.messages	Whether or not the output message is suppressed.
minimum.Funbound.plasma	Monte Carlo draws less than this value are set equal to this value (default is 0.0001 – half the lowest measured Fup in our dataset).
...	Other parameters

Value

BW	Body Weight, kg.
Clint	Hepatic intrinsic clearance, uL/min/10 ⁶ cells
Clint.dist	Distribution of hepatic intrinsic clearance values (median, lower 95th, upper 95th, p value)

Clmetabolismc	Hepatic Clearance, L/h/kg BW.
Fgutabs	Fraction of the oral dose absorbed, i.e. the fraction of the dose that enters the gut lumen.
Fhep.assay.correction	The fraction of chemical unbound in hepatocyte assay using the method of Kilford et al. (2008)
Funbound.plasma	Fraction of chemical unbound to plasma.
Funbound.plasma.adjustment	Fraction unbound to plasma adjusted as described in Pearce et al. 2017
Funbound.plasma.dist	Distribution of fraction unbound to plasma (median, lower 95th, upper 95th)
hematocrit	Percent volume of red blood cells in the blood.
Kblood2air	Ratio of concentration of chemical in blood to air
Kgut2pu	Ratio of concentration of chemical in gut tissue to unbound concentration in plasma.
kgutabs	Rate that chemical enters the gut from gutlumen, 1/h.
Kkidney2pu	Ratio of concentration of chemical in kidney tissue to unbound concentration in plasma.
Kliver2pu	Ratio of concentration of chemical in liver tissue to unbound concentration in plasma.
Klung2pu	Ratio of concentration of chemical in lung tissue to unbound concentration in plasma.
km	Michaelis-Menten concentration of half-maximal activity
Kmuc2air	Mucus to air partition coefficient
Krbc2pu	Ratio of concentration of chemical in red blood cells to unbound concentration in plasma.
Krest2pu	Ratio of concentration of chemical in rest of body tissue to unbound concentration in plasma.
kUrtc	Unscaled upper respiratory tract uptake parameter ($L/h/kg^{0.75}$)
liver.density	Density of liver in g/mL
MA	phospholipid:water distribution coefficient, membrane affinity
million.cells.per.gliver	Millions cells per gram of liver tissue.
MW	Molecular Weight, g/mol.
pKa_Accept	compound H association equilibrium constant(s)
pKa_Donor	compound H dissociation equilibrium constant(s)
Pow	octanol:water partition coefficient (not log transformed)
Qalvc	Unscaled alveolar ventilation rate ($L/h/kg^{0.75}$)
Qcardiac	Cardiac Output, $L/h/kg BW^{3/4}$.
Qgfr	Glomerular Filtration Rate, $L/h/kg BW^{0.75}$, volume of fluid filtered from kidney and excreted.
Qgutf	Fraction of cardiac output flowing to the gut.
Qkidneyf	Fraction of cardiac output flowing to the kidneys.

Qliverf	Fraction of cardiac output flowing to the liver.
Qlungf	Fraction of cardiac output flowing to lung tissue.
Qrestf	Fraction of blood flow to rest of body
Rblood2plasma	The ratio of the concentration of the chemical in the blood to the concentration in the plasma from available_rblood2plasma.
Vartc	Volume of the arteries per kg body weight, L/kg BW.
Vgutc	Volume of the gut per kg body weight, L/kg BW.
Vkidneyc	Volume of the kidneys per kg body weight, L/kg BW.
Vliverc	Volume of the liver per kg body weight, L/kg BW.
Vlungc	Volume of the lungs per kg body weight, L/kg BW.
vmax	Michaelis-Menten maximum reaction velocity (1/min)
Vmucc	Unscaled mucosal volume (L/kg BW ^{0.75})
Vrestc	Volume of the rest of the body per kg body weight, L/kg BW.
Vvenc	Volume of the veins per kg body weight, L/kg BW.

                    tissuelist=compartments)
```

parameterize_pbtok	<i>Parameters for a generic physiologically-based toxicokinetic model</i>
--------------------	---

Description

Generate a chemical- and species-specific set of model parameters, including tissue:plasma partition coefficients (via Schmitt (2008)'s method as modified by Pearce et al. (2017)) and organ volumes and flows (from table [physiology.data](#)) for an arbitrary tissue lumping scheme (tissues must be described in table [tissue.data](#)).

Usage

```
parameterize_pbtok(
  chem.cas = NULL,
  chem.name = NULL,
  dtxsid = NULL,
  species = "Human",
  default.to.human = FALSE,
  tissuelist = list(liver = c("liver"), kidney = c("kidney"), lung = c("lung"), gut =
    c("gut")),
  force.human.clint.fup = FALSE,
  clint.pvalue.threshold = 0.05,
  adjusted.Funbound.plasma = TRUE,
  adjusted.Clint = TRUE,
  regression = TRUE,
  suppress.messages = FALSE,
  restrictive.clearance = TRUE,
  minimum.Funbound.plasma = 1e-04
)
```

Arguments

chem.cas	Chemical Abstract Services Registry Number (CAS-RN) – the chemical must be identified by either CAS, name, or DTXISD
chem.name	Chemical name (spaces and capitalization ignored) – the chemical must be identified by either CAS, name, or DTXISD
dtxsid	EPA's 'DSSTox Structure ID (https://comptox.epa.gov/dashboard) – the chemical must be identified by either CAS, name, or DTXSIDs
species	Species desired (either "Rat", "Rabbit", "Dog", "Mouse", or default "Human").
default.to.human	Substitutes missing animal values with human values if true (hepatic intrinsic clearance or fraction of unbound plasma).
tissuelist	Specifies compartment names and tissues groupings. Remaining tissues in tissue.data are lumped in the rest of the body. However, solve_pbtok only works with the default parameters.
force.human.clint.fup	Forces use of human values for hepatic intrinsic clearance and fraction of unbound plasma if true.

<code>clint.pvalue.threshold</code>	Hepatic clearance for chemicals where the in vitro clearance assay result has a p-values greater than the threshold are set to zero.
<code>adjusted.Funbound.plasma</code>	Uses Pearce et al. (2017) lipid binding adjustment for Funbound.plasma (which impacts partition coefficients) when set to TRUE (Default).
<code>adjusted.Clint</code>	Uses Kilford et al. (2008) hepatocyte incubation binding adjustment for Clint when set to TRUE (Default).
<code>regression</code>	Whether or not to use the regressions in calculating partition coefficients.
<code>suppress.messages</code>	Whether or not the output message is suppressed.
<code>restrictive.clearance</code>	In calculating hepatic.bioavailability, protein binding is not taken into account (set to 1) in liver clearance if FALSE.
<code>minimum.Funbound.plasma</code>	Monte Carlo draws less than this value are set equal to this value (default is 0.0001 – half the lowest measured Fup in our dataset).

Details

By default, this function initializes the parameters needed in the functions [solve_pbt](#), [calc_css](#), and others using the httk default generic PBT model (for oral and intravenous dosing only).

Value

<code>BW</code>	Body Weight, kg.
<code>Clmetabolismc</code>	Hepatic Clearance, L/h/kg BW.
<code>Fgutabs</code>	Fraction of the oral dose absorbed, i.e. the fraction of the dose that enters the gutlumen.
<code>Funbound.plasma</code>	Fraction of plasma that is not bound.
<code>Fhep.assay.correction</code>	The fraction of chemical unbound in hepatocyte assay using the method of Kilford et al. (2008)
<code>hematocrit</code>	Percent volume of red blood cells in the blood.
<code>Kgut2pu</code>	Ratio of concentration of chemical in gut tissue to unbound concentration in plasma.
<code>kgutabs</code>	Rate that chemical enters the gut from gutlumen, 1/h.
<code>Kkidney2pu</code>	Ratio of concentration of chemical in kidney tissue to unbound concentration in plasma.
<code>Kliver2pu</code>	Ratio of concentration of chemical in liver tissue to unbound concentration in plasma.
<code>Klung2pu</code>	Ratio of concentration of chemical in lung tissue to unbound concentration in plasma.
<code>Krbc2pu</code>	Ratio of concentration of chemical in red blood cells to unbound concentration in plasma.
<code>Krest2pu</code>	Ratio of concentration of chemical in rest of body tissue to unbound concentration in plasma.

million.cells.per.gliver	Millions cells per gram of liver tissue.
MW	Molecular Weight, g/mol.
Qcardiac	Cardiac Output, L/h/kg BW ^{3/4} .
Qgfr	Glomerular Filtration Rate, L/h/kg BW ^{3/4} , volume of fluid filtered from kidney and excreted.
Qgut	Fraction of cardiac output flowing to the gut.
Qkidney	Fraction of cardiac output flowing to the kidneys.
Qliver	Fraction of cardiac output flowing to the liver.
Rblood2plasma	The ratio of the concentration of the chemical in the blood to the concentration in the plasma from available_rblood2plasma.
Vartc	Volume of the arteries per kg body weight, L/kg BW.
Vgut	Volume of the gut per kg body weight, L/kg BW.
Vkidney	Volume of the kidneys per kg body weight, L/kg BW.
Vliver	Volume of the liver per kg body weight, L/kg BW.
Vlung	Volume of the lungs per kg body weight, L/kg BW.
Vrest	Volume of the rest of the body per kg body weight, L/kg BW.
Vven	Volume of the veins per kg body weight, L/kg BW.

Examples

```
parameters <- parameterize_pbt(chem.cas='80-05-7')

parameters <- parameterize_pbt(chem.name='Bisphenol-A',species='Rat')

# Change the tissue lumping (note, these model parameters will not work with our current solver):
compartments <- list(liver=c("liver"),fast=c("heart","brain","muscle","kidney"),
                    lung=c("lung"),gut=c("gut"),slow=c("bone"))
parameterize_pbt(chem.name="Bisphenol a",species="Rat",default.to.human=TRUE,
                 tissuelist=compartments)
```

parameterize_schmitt *Parameters for Schmitt's (2008) Tissue Partition Coefficient Method*

Description

This function provides the necessary parameters to run `predict_partitioning_schmitt`, excluding the data in table `tissue.data`. The model is based on the Schmitt (2008) method for predicting tissue:plasma partition coefficients as modified by Pearce et al. (2017). The modifications include approaches adapted from Peyret et al. (2010).

Usage

```
parameterize_schmitt(
  chem.cas = NULL,
  chem.name = NULL,
  dtxsid = NULL,
  parameters = NULL,
  species = "Human",
  default.to.human = FALSE,
  force.human.fup = FALSE,
  adjusted.funbound.plasma = TRUE,
  suppress.messages = FALSE,
  minimum.funbound.plasma = 1e-04
)
```

Arguments

<code>chem.cas</code>	Chemical Abstract Services Registry Number (CAS-RN) – if parameters is not specified then the chemical must be identified by either CAS, name, or DTXISD
<code>chem.name</code>	Chemical name (spaces and capitalization ignored) – if parameters is not specified then the chemical must be identified by either CAS, name, or DTXISD
<code>dtxsid</code>	EPA's DSSTox Structure ID (https://comptox.epa.gov/dashboard) – if parameters is not specified then the chemical must be identified by either CAS, name, or DTXSIDs
<code>parameters</code>	Chemical and physiological description parameters needed to run the Schmitt et al. (2008) model
<code>species</code>	Species desired (either "Rat", "Rabbit", "Dog", "Mouse", or default "Human").
<code>default.to.human</code>	Substitutes missing fraction of unbound plasma with human values if true.
<code>force.human.fup</code>	Returns human fraction of unbound plasma in calculation for rats if true. When species is specified as rabbit, dog, or mouse, the human unbound fraction is substituted.
<code>adjusted.funbound.plasma</code>	Uses Pearce et al. (2017) lipid binding adjustment for Funbound.plasma (which impacts partition coefficients) when set to TRUE (Default).
<code>suppress.messages</code>	Whether or not the output message is suppressed.
<code>minimum.funbound.plasma</code>	Monte Carlo draws less than this value are set equal to this value (default is 0.0001 – half the lowest measured Fup in our dataset).

Value

Funbound.plasma	Unbound fraction in plasma, adjusted for lipid binding according to Pearce et al. (2017)
unadjusted.Funbound.plasma	measured unbound fraction in plasma (0.005 if below limit of detection)
Pow	octanol:water partition coefficient (not log transformed)
pKa_Donor	compound H dissociation equilibrium constant(s)
pKa_Accept	compound H association equilibrium constant(s)
MA	phospholipid:water distribution coefficient, membrane affinity
Fprotein.plasma	protein fraction in plasma
plasma.pH	pH of the plasma

```
parameterize_steadystate
```

Parameters for a three-compartment toxicokinetic model at steady-state

Description

This function initializes the parameters needed in the functions `calc_mc_css`, `calc_mc_oral_equiv`, and `calc_analytic_css` for the three compartment steady state model ('3compartmentss') as used in Rotroff et al. (2010), Wetmore et al. (2012), Wetmore et al. (2015), and elsewhere. By assuming that enough time has passed to reach steady-state, we eliminate the need for tissue-specific partition coefficients because we assume all tissues have come to equilibrium with the unbound concentration in plasma. However, we still use chemical properties to predict the blood:plasma ratio for estimating first-pass hepatic metabolism for oral exposures.

Usage

```
parameterize_steadystate(
  chem.cas = NULL,
  chem.name = NULL,
  dtxsid = NULL,
  species = "Human",
  clint.pvalue.threshold = 0.05,
  default.to.human = FALSE,
  human.clint.fup = FALSE,
  adjusted.Funbound.plasma = TRUE,
  adjusted.Clint = TRUE,
  restrictive.clearance = TRUE,
  fup.lod.default = 0.005,
  suppress.messages = FALSE,
  minimum.Funbound.plasma = 1e-04
)
```

Arguments

chem.cas	Chemical Abstract Services Registry Number (CAS-RN) – the chemical must be identified by either CAS, name, or DTXISD
chem.name	Chemical name (spaces and capitalization ignored) – the chemical must be identified by either CAS, name, or DTXISD
dtxsid	EPA's DSSTox Structure ID (https://comptox.epa.gov/dashboard) – the chemical must be identified by either CAS, name, or DTXISDs
species	Species desired (either "Rat", "Rabbit", "Dog", "Mouse", or default "Human").
clint.pvalue.threshold	Hepatic clearances with clearance assays having p-values greater than the threshold are set to zero.
default.to.human	Substitutes missing rat values with human values if true.
human.clint.fup	Uses human hepatic intrinsic clearance and fraction of unbound plasma in calculation of partition coefficients for rats if true.
adjusted.Funbound.plasma	Uses Pearce et al. (2017) lipid binding adjustment for Funbound.plasma (which impacts partition coefficients) when set to TRUE (Default).
adjusted.Clint	Uses Kilford et al. (2008) hepatocyte incubation binding adjustment for Clint when set to TRUE (Default).
restrictive.clearance	In calculating hepatic.bioavailability, protein binding is not taken into account (set to 1) in liver clearance if FALSE.
fup.lod.default	Default value used for fraction of unbound plasma for chemicals where measured value was below the limit of detection. Default value is 0.0005.
suppress.messages	Whether or not the output message is suppressed.
minimum.Funbound.plasma	Monte Carlo draws less than this value are set equal to this value (default is 0.0001 – half the lowest measured Fup in our dataset).

Value

Clint	Hepatic Intrinsic Clearance, uL/min/10 ⁶ cells.
Fgutabs	Fraction of the oral dose absorbed, i.e. the fraction of the dose that enters the gutlumen.
Funbound.plasma	Fraction of plasma that is not bound.
Qtotall.liverc	Flow rate of blood exiting the liver, L/h/kg BW ^{3/4} .
Qgfrc	Glomerular Filtration Rate, L/h/kg BW ^{3/4} , volume of fluid filtered from kidney and excreted.
BW	Body Weight, kg
MW	Molecular Weight, g/mol
million.cells.per.gliver	Millions cells per gram of liver tissue.
Vliverc	Volume of the liver per kg body weight, L/kg BW.
liver.density	Liver tissue density, kg/L.
Fhep.assay.correction	The fraction of chemical unbound in hepatocyte assay using the method of Kilford et al. (2008)
hepatic.bioavailability	Fraction of dose remaining after first pass clearance, calculated from the corrected well-stirred model.

predict_partitioning_schmitt

Predict partition coefficients using the method from Schmitt (2008).

Description

This function implements the method from Schmitt (2008) in predicting the tissue to unbound plasma partition coefficients for the tissues contained in the tissue.data table.

Usage

```
predict_partitioning_schmitt(  
  chem.name = NULL,  
  chem.cas = NULL,  
  dtxsid = NULL,  
  species = "Human",  
  model = "pbtk",  
  default.to.human = FALSE,  
  parameters = NULL,  
  alpha = 0.001,  
  adjusted.funbound.plasma = TRUE,  
  regression = TRUE,  
  regression.list = c("brain", "adipose", "gut", "heart", "kidney", "liver", "lung",  
    "muscle", "skin", "spleen", "bone"),  
  tissues = NULL,  
  minimum.funbound.plasma = 1e-04,  
  suppress.messages = FALSE  
)
```

Arguments

chem.name	Either the chemical name or the CAS number must be specified.
chem.cas	Either the chemical name or the CAS number must be specified.
dtxsid	EPA's DSSTox Structure ID (https://comptox.epa.gov/dashboard) the chemical must be identified by either CAS, name, or DTXSIDs
species	Species desired (either "Rat", "Rabbit", "Dog", "Mouse", or default "Human").
model	Model for which partition coefficients are needed (for example, "pbtk", "3compartment")

default.to.human	Substitutes missing animal values with human values if true (hepatic intrinsic clearance or fraction of unbound plasma).
parameters	Chemical parameters from parameterize_schmitt overrides chem.name, dtxsid, and chem.cas.
alpha	Ratio of Distribution coefficient D of totally charged species and that of the neutral form
adjusted.funbound.plasma	Whether or not to use Funbound.plasma adjustment.
regression	Whether or not to use the regressions. Regressions are used by default.
regression.list	Tissues to use regressions on.
tissues	Vector of desired partition coefficients. Returns all by default.
minimum.funbound.plasma	Monte Carlo draws less than this value are set equal to this value (default is 0.0001 – half the lowest measured Fup in our dataset).
suppress.messages	Whether or not the output message is suppressed.

Details

A separate regression is used when adjusted.funbound.plasma is FALSE.

A regression is used for membrane affinity when not provided. The regressions for correcting each tissue are performed on tissue plasma partition coefficients ($K_{\text{tissue2pu}} * \text{Funbound.plasma}$) calculated with the corrected Funbound.plasma value and divided by this value to get $K_{\text{tissue2pu}}$. Thus the regressions should be used with the corrected Funbound.plasma.

The red blood cell regression can be used but is not by default because of the span of the data used, reducing confidence in the regression for higher and lower predicted values.

Human tissue volumes are used for species other than Rat.

Value

Returns tissue to unbound plasma partition coefficients for each tissue.

pregnonpregaucs

*AUCs for Pregnant and Non-Pregnant Women***Description**

Dallmann et al. (2018) includes compiled literature descriptions of toxicokinetic summary statistics, including time-integrated plasma concentrations (area under the curve or AUC) for drugs administered to a sample of subjects including both pregnant and non-pregnant women. The circumstances of the dosing varied slightly between drugs and are summarized in the table.

Usage

```
pregnonpregaucs
```

Format

```
data.frame
```

```
propagate_invitrouv_1comp
```

Propagates uncertainty and variability in in vitro HTTK data into one compartment model parameters

Description

Propagates uncertainty and variability in in vitro HTTK data into one compartment model parameters

Usage

```
propagate_invitrouv_1comp(parameters.dt, ...)
```

Arguments

`parameters.dt` The data table of parameters being used by the Monte Carlo sampler
`...` Additional arguments passed to `calc_elimination_rate`

Value

A data.table whose columns are the parameters of the HTTK model specified in model.

Author(s)

John Wambaugh

propagate_invitrouv_3comp

Propagates uncertainty and variability in in vitro HTTK data into three compartment model parameters

Description

Propagates uncertainty and variability in in vitro HTTK data into three compartment model parameters

Usage

```
propagate_invitrouv_3comp(parameters.dt, ...)
```

Arguments

parameters.dt The data table of parameters being used by the Monte Carlo sampler
... Additional arguments passed to [calc_hep_clearance](#)

Value

A data.table whose columns are the parameters of the HTTK model specified in model.

Author(s)

John Wambaugh

propagate_invitrouv_pbt

Propagates uncertainty and variability in in vitro HTTK data into PBPK model parameters

Description

Propagates uncertainty and variability in in vitro HTTK data into PBPK model parameters

Usage

```
propagate_invitrouv_pbt(parameters.dt, ...)
```

Arguments

`parameters.dt` The data table of parameters being used by the Monte Carlo sampler
... Additional arguments passed to [calc_hep_clearance](#)

Value

A `data.table` whose columns are the parameters of the HHTK model specified in `model`.

Author(s)

John Wambaugh

reset_httk	<i>Reset HHTK to Default Data Tables</i>
------------	--

Description

This function returns an updated version of `chem.physical_and_invitro.data` that includes data predicted with Simulations Plus' ADMET predictor that was used in Sipes et al. 2017, included in `admet.data`.

Usage

```
reset_httk(target.env = .GlobalEnv)
```

Arguments

`target.env` The environment where the new `chem.physical_and_invitro.data` is loaded. Defaults to global environment.

Value

`data.frame` The package default version of `chem.physical_and_invitro.data`.

Author(s)

John Wambaugh

Examples

```
chem.physical_and_invitro.data <- load_sipes2017()
reset_httk()
```

rfun	<i>Randomly draws from a one-dimensional KDE</i>
------	--

Description

Randomly draws from a one-dimensional KDE

Usage

rfun(n, fhat)

Arguments

- n Number of samples to draw
- fhat A list with elements x, w, and h (h is the KDE bandwidth).

Value

A vector of n samples from the KDE fhat

Author(s)

Caroline Ring

Ring, Caroline L., et al. "Identifying populations sensitive to environmental chemicals by simulating toxicokinetic variability." *Environment International* 106 (2017): 105-118

rmed0non0u95	<i>Draw random numbers with LOD median but non-zero upper 95th percentile</i>
--------------	---

Description

This function draws N random numbers from a distribution that approximates a median that is equal to the limit of detection (LOD, value x.LOD) but has an upper 95th percentile (x.u95) that is above x.LOD. We make the assumption that values above x.u95 are uniformly distributed between x.u95 and x.u95 + (x.u95 - x.LOD)

Usage

rmed0non0u95(n, x.u95, x.min = 0, x.LOD = 0.005)

Arguments

- n Number of samples to draw
- x.u95 The upper limit on the 95th confidence/credible intervale (this is the 97.5 percentile)
- x.min The minimum allowed value (defaults to 0)
- x.LOD The limit of detection (defaults to 0.005)

Value

A vector of N samples where the 50th and 97.5th quantiles approximate x.LOD and x.u95 respectively

Author(s)

John Wambaugh

References

Breen et al., in preparation

Examples

```
Fup.95 <- 0.02
N <- 1000

set.seed(1235)
Fup.vec <- rmed0non0u95(n=N, x.u95=Fup.95)
quantile(Fup.vec, c(0.5, 0.975))

quantile(rmed0non0u95(200, x.u95=0.05, x.min=10^-4, x.LOD=0.01), c(0.5, 0.975))
hist(rmed0non0u95(1000, x.u95=0.05, x.min=10^-4, x.LOD=0.01))

quantile(rmed0non0u95(200, x.u95=0.005, x.min=10^-4, x.LOD=0.01), c(0.5, 0.975))
hist(rmed0non0u95(1000, x.u95=0.005, x.min=10^-4, x.LOD=0.01))
```

r_left_censored_norm	<i>Returns draws from a normal distribution with a lower censoring limit of lod (limit of detection)</i>
----------------------	--

Description

Returns draws from a normal distribution with a lower censoring limit of lod (limit of detection)

Usage

```
r_left_censored_norm(n, mean = 0, sd = 1, lod = 0.005, lower = 0, upper = 1)
```

Arguments

n	Number of samples to take
mean	Mean of censored distribution. Default 0.
sd	Standard deviation of censored distribution. Default 1.
lod	Bound below which to censor. Default 0.005.
lower	Lower bound on censored distribution. Default 0.
upper	Upper bound on censored distribution. Default 1.

Value

A vector of samples from the specified censored distribution.

scale_dosing

*Scale mg/kg body weight doses according to body weight and units***Description**

This function transforms the dose (in mg/kg) into the appropriate units. It handles single doses, matrices of doses, or daily repeated doses at varying intervals. Gut absorption is also factored in through the parameter Fgutabs, and scaling is currently avoided in the inhalation exposure case with a scale factor of 1

Usage

```
scale_dosing(
  dosing,
  parameters,
  route,
  input.units = NULL,
  output.units = "uM",
  vol = NULL
)
```

Arguments

dosing	List of dosing metrics used in simulation, which must include the general entries with names "initial.dose", "doses.per.day", "daily.dose", and "dosing.matrix". The "dosing.matrix" is used for more precise dose regimen specification, and is a matrix consisting of two columns or rows named "time" and "dose" containing the time and amount, in mg/kg BW, of each dose. The minimal usage case involves all entries but "initial.dose" set to NULL in value.
parameters	Chemical parameters from parameterize_pbt function, overrides chem.name and chem.cas.
route	String specification of route of exposure for simulation: "oral", "iv", "inhalation", ...
input.units	Units of the dose values being scaled. (Default is NULL.) Currently supported units "mg/L", "ug/L", "ug/mL", "uM", "umol/L", "ug/dL", "ug/g", "nmol/L", "nM", and "ppmw" (supported input.units subject to change).
output.units	Desired units (either "mg/L", "mg", "umol", or default "uM").
vol	Volume for the target tissue of interest. NOTE: Volume should not be in units of per BW, i.e. "kg".

Value

A list of numeric values for doses converted to output.units, potentially (depending on argument dosing) including:

initial.dose	The first dose given
dosing.matrix	A 2xN matrix where the first column is dose time and the second is dose amount for N doses
daily.dose	The total cumulative daily dose

Author(s)

John Wambaugh and Sarah E. Davidson

scr_h	<i>KDE bandwidths for residual variability in serum creatinine</i>
-------	--

Description

Bandwidths used for a one-dimensional kernel density estimation of the distribution of residual errors around smoothing spline fits of serum creatinine vs. age for NHANES respondents in each of ten combinations of sex and race/ethnicity categories.

Usage

scr_h

Format

A named list with 10 elements, each a numeric value. Each list element corresponds to, and is named for, one combination of NHANES sex categories (Male and Female) and NHANES race/ethnicity categories (Mexican American, Other Hispanic, Non-Hispanic White, Non-Hispanic Black, and Other).

Details

Each matrix is the standard deviation for a normal distribution: this is the bandwidth to be used for a kernel density estimation (KDE) (using a normal kernel) of the distribution of residual errors around smoothing spline fits of serum creatinine vs. age for NHANES respondents in the specified sex and race/ethnicity category. Optimal bandwidths were pre-calculated by doing the smoothing spline fits, getting the residuals, then calling [kde](#) on the residuals (which calls [hpi](#) to compute the plug-in bandwidth).

Used by HTTK-Pop only in "virtual individuals" mode (i.e. [httkpop_generate](#) with method = "v"), in [gen_serum_creatinine](#).

set_httk_precision	<i>set_httk_precision</i>
--------------------	---------------------------

Description

Although the ODE solver and other functions return very precise numbers, we cannot (or at least do not spend enough computing time to) be sure of the precision to an arbitrary level. This function both limits the number of significant figures reported and truncates the numerical precision.

Usage

```
set_httk_precision(in.num, sig.fig = 4, num.prec = 9)
```

Arguments

in.num	The numeric variable (or assembly of numerics) to be processed.
sig.fig	The number of significant figures reported. Defaults to 4.
num.prec	The precision maintained, digits below $10^{\text{num.prec}}$ are dropped. Defaults to 9.

Value

numeric values

Author(s)

John Wambaugh

skeletal_muscle_mass	<i>Predict skeletal muscle mass</i>
----------------------	-------------------------------------

Description

Predict skeletal muscle mass from age, height, and gender.

Usage

```
skeletal_muscle_mass(smm, age_years, height, gender)
```

Arguments

smm	Vector of allometrically-scaled skeletal muscle masses.
age_years	Vector of ages in years.
height	Vector of heights in cm.
gender	Vector of genders, either 'Male' or 'Female.'

Details

For individuals over age 18, use allometrically-scaled muscle mass with an age-based scaling factor, to account for loss of muscle mass with age (Janssen et al. 2000). For individuals under age 18, use [skeletal_muscle_mass_children](#).

Value

Vector of skeletal muscle masses in kg.

Author(s)

Caroline Ring

skeletal_muscle_mass_children

Predict skeletal muscle mass for children

Description

For individuals under age 18, predict skeletal muscle mass from gender and age, using a nonlinear equation from Webber and Barr (2012)

Usage

```
skeletal_muscle_mass_children(gender, age_years)
```

Arguments

gender	Vector of genders (either 'Male' or 'Female').
age_years	Vector of ages in years.

Value

Vector of skeletal muscle masses in kg.

Author(s)

Caroline Ring

skin_mass_bosgra	<i>Predict skin mass</i>
------------------	--------------------------

Description

Using equation from Bosgra et al. 2012, predict skin mass from body surface area.

Usage

```
skin_mass_bosgra(BSA)
```

Arguments

BSA Vector of body surface areas in cm².

Value

Vector of skin masses in kg.

solve_1comp	<i>Solve one compartment TK model</i>
-------------	---------------------------------------

Description

This function solves for the amount or concentration of a chemical in plasma for a one compartment model as a function of time based on the dose and dosing frequency.

Usage

```
solve_1comp(  
  chem.name = NULL,  
  chem.cas = NULL,  
  dtxsid = NULL,  
  times = NULL,  
  parameters = NULL,  
  days = 10,  
  tsteps = 4,  
  daily.dose = NULL,
```

```

dose = NULL,
doses.per.day = NULL,
initial.values = NULL,
plots = FALSE,
suppress.messages = FALSE,
species = "Human",
iv.dose = FALSE,
input.units = "mg/kg",
output.units = NULL,
method = "lsoda",
rtol = 1e-08,
atol = 1e-12,
default.to.human = FALSE,
recalc.blood2plasma = FALSE,
recalc.clearance = FALSE,
dosing.matrix = NULL,
adjusted.funbound.plasma = TRUE,
regression = TRUE,
restrictive.clearance = TRUE,
minimum.funbound.plasma = 1e-04,
monitor.vars = NULL,
...
)

```

Arguments

chem.name	Either the chemical name, CAS number, or the parameters must be specified.
chem.cas	Either the chemical name, CAS number, or the parameters must be specified.
dtxsid	EPA's 'DSSTox Structure ID (https://comptox.epa.gov/dashboard) the chemical must be identified by either CAS, name, or DTXSIDs
times	Optional time sequence for specified number of days.
parameters	Chemical parameters from parameterize_1comp function, overrides chem.name and chem.cas.
days	Length of the simulation.
tsteps	The number time steps per hour.
daily.dose	Total daily dose, default is mg/kg BW.
dose	Amount of a single dose, default is mg/kg BW.
doses.per.day	Number of doses per day.
initial.values	Vector containing the initial concentrations or amounts of the chemical in specified tissues with units corresponding to output.units. Defaults are zero.
plots	Plots all outputs if true.
suppress.messages	Whether or not the output message is suppressed.
species	Species desired (either "Rat", "Rabbit", "Dog", or default "Human").
iv.dose	Simulates a single i.v. dose if true.
input.units	Input units of interest assigned to dosing, defaults to "mg/kg" BW.
output.units	A named vector of output units expected for the model results. Default, NULL, returns model results in units specified in the 'modelinfo' file. See table below for details.

<code>method</code>	Method used by integrator (deSolve).
<code>rtol</code>	Argument passed to integrator (deSolve).
<code>atol</code>	Argument passed to integrator (deSolve).
<code>default.to.human</code>	Substitutes missing rat values with human values if true.
<code>recalc.blood2plasma</code>	Whether or not to recalculate the blood:plasma chemical concentration ratio
<code>recalc.clearance</code>	Whether or not to recalculate the elimination rate.
<code>dosing.matrix</code>	Vector of dosing times or a matrix consisting of two columns or rows named "dose" and "time" containing the time and amount, in mg/kg BW by default, of each dose.
<code>adjusted.Funbound.plasma</code>	Uses adjusted Funbound.plasma when set to TRUE along with volume of distribution calculated with this value.
<code>regression</code>	Whether or not to use the regressions in calculating partition coefficients in volume of distribution calculation.
<code>restrictive.clearance</code>	In calculating elimination rate, protein binding is not taken into account (set to 1) in liver clearance if FALSE.
<code>minimum.Funbound.plasma</code>	Monte Carlo draws less than this value are set equal to this value (default is 0.0001 – half the lowest measured Fup in our dataset).
<code>monitor.vars</code>	Which variables are returned as a function of time. Defaults value of NULL provides "Agutlumen", "Ccompartment", "Ametabolized", "AUC"
<code>...</code>	Additional arguments passed to the integrator.

Details

Note that the model parameters have units of hours while the model output is in days.

Default value of NULL for `doses.per.day` solves for a single dose.

When species is specified as rabbit, dog, or mouse, the function uses the appropriate physiological data (volumes and flows) but substitutes human fraction unbound, partition coefficients, and intrinsic hepatic clearance.

AUC is area under plasma concentration curve.

Model Figure

altalt

Value

A matrix with a column for time(in days) and a column for the compartment and the area under the curve (concentration only).

Author(s)

Robert Pearce

References

Pearce, Robert G., et al. "Htk: R package for high-throughput toxicokinetics." Journal of statistical software 79.4 (2017): 1.

Examples

```
solve_1comp(chem.name='Bisphenol-A',days=1)
params <- parameterize_1comp(chem.cas="80-05-7")
solve_1comp(parameters=params)
```

solve_3comp

Solve_3comp

Description

This function solves for the amounts or concentrations of a chemical in different tissues as functions of time based on the dose and dosing frequency. It uses a three compartment model with partition coefficients.

Usage

```
solve_3comp(
  chem.name = NULL,
  chem.cas = NULL,
  dtxsid = NULL,
  times = NULL,
  parameters = NULL,
  days = 10,
  tsteps = 4,
  daily.dose = NULL,
  dose = NULL,
  doses.per.day = NULL,
  initial.values = NULL,
  plots = FALSE,
  suppress.messages = FALSE,
  species = "Human",
  iv.dose = FALSE,
  input.units = "mg/kg",
  output.units = NULL,
  method = "lsoda",
  rtol = 1e-08,
  atol = 1e-12,
  default.to.human = FALSE,
  recalc.blood2plasma = FALSE,
  recalc.clearance = FALSE,
  dosing.matrix = NULL,
  adjusted.funbound.plasma = TRUE,
  regression = TRUE,
  restrictive.clearance = TRUE,
  minimum.funbound.plasma = 1e-04,
  monitor.vars = NULL,
  ...
)
```

Arguments

chem.name	Either the chemical name, CAS number, or the parameters must be specified.
chem.cas	Either the chemical name, CAS number, or the parameters must be specified.
dtxsid	EPA's 'DSSTox Structure ID (https://comptox.epa.gov/dashboard) the chemical must be identified by either CAS, name, or DTXSIDs
times	Optional time sequence for specified number of days. The dosing sequence begins at the beginning of times.
parameters	Chemical parameters from parameterize_3comp function, overrides chem.name and chem.cas.
days	Length of the simulation.
tsteps	The number time steps per hour.
daily.dose	Total daily dose, mg/kg BW.
dose	Amount of a single dose, mg/kg BW.
doses.per.day	Number of doses per day.
initial.values	Vector containing the initial concentrations or amounts of the chemical in specified tissues with units corresponding to output.units. Defaults are zero.
plots	Plots all outputs if true.
suppress.messages	Whether or not the output message is suppressed.
species	Species desired (either "Rat", "Rabbit", "Dog", "Mouse", or default "Human").
iv.dose	Simulates a single i.v. dose if true.
input.units	Input units of interest assigned to dosing, defaults to mg/kg BW
output.units	A named vector of output units expected for the model results. Default, NULL, returns model results in units specified in the 'modelinfo' file. See table below for details.
method	Method used by integrator (deSolve).
rtol	Argument passed to integrator (deSolve).
atol	Argument passed to integrator (deSolve).
default.to.human	Substitutes missing animal values with human values if true (hepatic intrinsic clearance or fraction of unbound plasma).
recalc.blood2plasma	Recalculates the ratio of the amount of chemical in the blood to plasma using the input parameters, calculated with hematocrit, Funbound.plasma, and Krbc2pu.
recalc.clearance	Recalculates the the hepatic clearance (Clmetabolism) with new million.cells.per.g liver parameter.
dosing.matrix	Vector of dosing times or a matrix consisting of two columns or rows named "dose" and "time" containing the time and amount, in mg/kg BW, of each dose.
adjusted.Funbound.plasma	Uses adjusted Funbound.plasma when set to TRUE along with partition coefficients calculated with this value.
regression	Whether or not to use the regressions in calculating partition coefficients.
restrictive.clearance	Protein binding not taken into account (set to 1) in liver clearance if FALSE.

<code>minimum.funbound.plasma</code>	Monte Carlo draws less than this value are set equal to this value (default is 0.0001 – half the lowest measured <i>F_{up}</i> in our dataset).
<code>monitor.vars</code>	Which variables are returned as a function of time. Defaults value of NULL provides "Cliver", "Csyscomp", "Atubules", "Ametabolized", "AUC"
<code>...</code>	Additional arguments passed to the integrator.

Details

Note that the model parameters have units of hours while the model output is in days.

Default of NULL for `doses.per.day` solves for a single dose.

The compartments used in this model are the gutlumen, gut, liver, and rest-of-body, with the plasma equivalent to the liver plasma.

Model Figure

altalt

When species is specified as rabbit, dog, or mouse, the function uses the appropriate physiological data(volumes and flows) but substitutes human fraction unbound, partition coefficients, and intrinsic hepatic clearance.

Value

A matrix of class `deSolve` with a column for time(in days) and each compartment, the plasma concentration, area under the curve, and a row for each time point.

```

```

    monitor.vars = NULL,
    ...
)

```

Arguments

chem.name	Either the chemical name, CAS number, or the parameters must be specified.
chem.cas	Either the chemical name, CAS number, or the parameters must be specified.
dtxsid	EPA's DSSTox Structure ID (http://comptox.epa.gov/dashboard) the chemical must be identified by either CAS, name, or DTXIDs
times	Optional time sequence in days. Dosing sequence begins at the beginning of times. Default is from 13th week of pregnancy to 40th due to data constraints.
parameters	Chemical parameters from parameterize_fetal_pbt function, overrides chem.name and chem.cas.
days	Length of the simulation.
species	Included for compatibility with other functions, but the model will not run for non-human species (default "Human").
tsteps	The number time steps per hour. Default of 4.
dose	Amount of a single dose, mg/kg BW.
dosing.matrix	A matrix of either one column (or row) with a set of dosing times or with two columns (or rows) correspondingly named "dose" and "time" containing the time and amount, in mg/kg BW, of each dose.
daily.dose	Total daily dose, mg.
doses.per.day	Number of doses per day.
initial.values	Vector containing the initial concentrations or amounts of the chemical in specified tissues with units corresponding to compartment.units. Defaults are zero.
plots	Plots all outputs if true.
suppress.messages	Whether or not the output message is suppressed.
iv.dose	Simulates a single i.v. dose if true.
input.units	Input units of interest assigned to dosing, defaults to mg/kg BW
output.units	A named vector of output units expected for the model results. Default, NULL, returns model results in units specified in the 'modelinfo' file. See table below for details.
method	Method used by integrator (deSolve).
rtol	Argument passed to integrator (deSolve).
atol	Argument passed to integrator (deSolve).
default.to.human	Substitutes missing animal values with human values if true (hepatic intrinsic clearance or fraction of unbound plasma).
recalc.blood2plasma	Recalculates the ratio of the amount of chemical in the blood to plasma using the input parameters, calculated with hematocrit, Funbound.plasma, and Krbc2pu.
recalc.clearance	Recalculates the the hepatic clearance (Clmetabolism) with new million.cells.per.g liver parameter.

```

adjusted.funbound.plasma
    Uses adjusted Funbound.plasma when set to TRUE along with partition coefficients calculated with this value.

regression
    Whether or not to use the regressions in calculating partition coefficients.

restrictive.clearance
    Protein binding not taken into account (set to 1) in liver clearance if FALSE.

minimum.funbound.plasma
    Monte Carlo draws less than this value are set equal to this value (default is 0.0001 – half the lowest measured Fup in our dataset).

monitor.vars
    Which variables to track by default

...
    Additional arguments passed to the integrator.

```

Details

The stage of pregnancy simulated here begins by default at the 13th week due to a relative lack of data to support parameterization prior, in line with the recommendations of Kapraun et al. 2019 ("Empirical models for anatomical and physiological..."), and ends at the 40th week of pregnancy.

Note that the model parameters have units of hours while the model output is in days. Dose is in mg, not scaled for body weight.

Default NULL value for doses.per.day solves for a single dose.

The maternal compartments used in this model are the gut lumen, gut, liver, venous blood, arterial blood, lung, adipose tissue, kidney, thyroid, and rest of body. A placenta is modeled as a joint organ shared by mother and fetus, through which chemical exchange can occur with the fetus. Fetal compartments include arterial blood, venous blood, kidney, thyroid, liver, lung, gut, brain, and rest of body.

The extra compartments include the amounts or concentrations metabolized by the liver and excreted by the kidneys through the tubules.

AUC is the area under the curve of the plasma concentration.

This gestational model is only parameterized for humans.

Value

A matrix of class `deSolve` with a column for time(in days), each compartment, the area under the curve, and plasma concentration and a row for each time point.

Author(s)

John Wambaugh, Mark Sfeir, and Dustin Kapraun

Examples

  fR = 12,  
  VT = 0.75,  
  VD = 0.15,
```

```
    ...
)
```

Arguments

chem.name	Either the chemical name, CAS number, or the parameters must be specified.
chem.cas	Either the chemical name, CAS number, or the parameters must be specified.
dtxsid	EPA's DSSTox Structure ID (https://comptox.epa.gov/dashboard) the chemical must be identified by either CAS, name, or DTXIDs
parameters	Chemical parameters from parameterize_gas_pbt (or other bespoke) function, overrides chem.name and chem.cas.
times	Optional time sequence for specified number of days. Dosing sequence begins at the beginning of times.
days	Length of the simulation.
tsteps	The number of time steps per hour.
daily.dose	Total daily dose
doses.per.day	Number of doses per day.
dose	Amount of a single dose
dosing.matrix	Vector of dosing times or a matrix consisting of two columns or rows named "dose" and "time" containing the time and amount of each dose.
forcings	Manual input of 'forcings' data series argument for ode integrator. If left unspecified, 'forcings' defaults to NULL, and then other input parameters (see exp.start.time, exp.conc, exp.duration, and period) provide the necessary information to assemble a forcings data series.
exp.start.time	Start time in specifying forcing exposure series, default 0.
exp.conc	Specified inhalation exposure concentration for use in assembling "forcings" data series argument for integrator. Defaults to units of ppmv.
period	For use in assembling forcing function data series 'forcings' argument, specified in hours
exp.duration	For use in assembling forcing function data series 'forcings' argument, specified in hours
initial.values	Vector containing the initial concentrations or amounts of the chemical in specified tissues with units corresponding to those specified for the model outputs. Default values are zero.
plots	Plots all outputs if true.
suppress.messages	Whether or not the output message is suppressed.
species	Species desired (either "Rat", "Rabbit", "Dog", "Mouse", or default "Human").
iv.dose	Simulates a single i.v. dose if true.
input.units	Input units of interest assigned to dosing, including forcings. Defaults to "ppmv" as applied to the default forcings scheme.
output.units	A named vector of output units expected for the model results. Default, NULL, returns model results in units specified in the 'modelinfo' file. See table below for details.
method	Method used by integrator (deSolve).
rtol	Argument passed to integrator (deSolve).

<code>atol</code>	Argument passed to integrator (deSolve).
<code>default.to.human</code>	Substitutes missing animal values with human values if true (hepatic intrinsic clearance or fraction of unbound plasma).
<code>recalc.blood2plasma</code>	Recalculates the ratio of the amount of chemical in the blood to plasma using the input parameters, calculated with hematocrit, <code>Funbound.plasma</code> , and <code>Krbc2pu</code> .
<code>recalc.clearance</code>	Recalculates the hepatic clearance (<code>Clmetabolism</code>) with new <code>million.cells.per.gliver</code> parameter.
<code>adjusted.Funbound.plasma</code>	Uses adjusted <code>Funbound.plasma</code> when set to TRUE along with partition coefficients calculated with this value.
<code>regression</code>	Whether or not to use the regressions in calculating partition coefficients.
<code>restrictive.clearance</code>	Protein binding not taken into account (set to 1) in liver clearance if FALSE.
<code>minimum.Funbound.plasma</code>	Monte Carlo draws less than this value are set equal to this value (default is 0.0001 – half the lowest measured <code>Fup</code> in our dataset).
<code>monitor.vars</code>	Which variables are returned as a function of time. Defaults value of NULL provides "Cgut", "Cliver", "Cven", "Clung", "Cart", "Crest", "Ckidney", "Cplasma", "Calv", "Cendexh", "Cmixexh", "Cmuc", "Atubules", "Ametabolized", "AUC"
<code>vmax</code>	Michaelis-Menten <code>vmax</code> value in reactions/min
<code>km</code>	Michaelis-Menten concentration of half-maximal reaction velocity in desired output concentration units.
<code>exercise</code>	Logical indicator of whether to simulate an exercise-induced heightened respiration rate
<code>fR</code>	Respiratory frequency (breaths/minute), used especially to adjust breathing rate in the case of exercise. This parameter, along with <code>VT</code> and <code>VD</code> (below) gives another option for calculating <code>Qalv</code> (Alveolar ventilation) in case pulmonary ventilation rate is not known
<code>VT</code>	Tidal volume (L), to be modulated especially as part of simulating the state of exercise
<code>VD</code>	Anatomical dead space (L), to be modulated especially as part of simulating the state of exercise
<code>...</code>	Additional arguments passed to the integrator.

Details

The default dosing scheme involves a specification of the start time of exposure (`exp.start.time`), the concentration of gas inhaled (`exp.conc`), the period of a cycle of exposure and non-exposure (`period`), the duration of the exposure during that period (`exp.duration`), and the total days simulated. Together, these arguments determine the "forcings" passed to the ODE integrator. Forcings can also be specified manually, or effectively turned off by setting exposure concentration to zero, if the user prefers to simulate dosing by other means.

The "forcings" object is configured to be passed to the integrator with, at the most, a basic unit conversion among ppmv, mg/L, and uM. No scaling by BW is set to be performed on the forcings series.

Note that the model parameters have units of hours while the model output is in days.

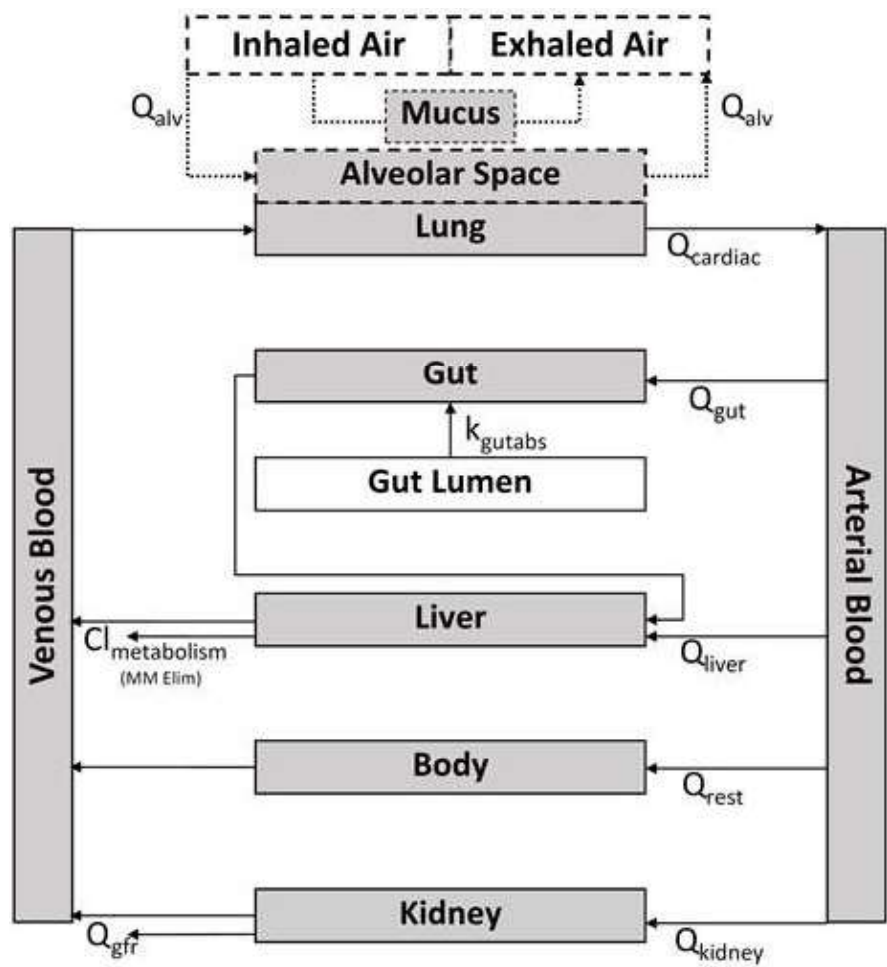

Default NULL value for doses.per.day solves for a single dose.

The compartments used in this model are the gut lumen, gut, liver, kidneys, veins, arteries, lungs, and the rest of the body.

The extra compartments include the amounts or concentrations metabolized by the liver and excreted by the kidneys through the tubules.

AUC is the area under the curve of the plasma concentration.

Model Figure from (Linakis et al. 2020):

altalt

Model parameters are named according to the following convention:

prefix	suffic	Meaning	units
K		Partition coefficient for tissue to free plasma \ tab	unitless
V		Volume	L

Q		Flow	L/h
k		Rate	1/h
c	Parameter is proportional to body weight	1 / kg for volumes and 1/kg ^(3/4) for flows	

When species is specified but chemical-specific in vitro data are not available, the function uses the appropriate physiological data (volumes and flows) but `default.to.human = TRUE` must be used to substitute human fraction unbound, partition coefficients, and intrinsic hepatic clearance.

Value

A matrix of class `deSolve` with a column for time(in days), each compartment, the area under the curve, and plasma concentration and a row for each time point.

daily.dose = 3, input.units = "umol", plots=TRUE,initial.values=c(Aven=20))

out <- solve_gas_pbt(chem.name = 'pyrene',exp.conc = 3, period = 24,
exp.duration = 6, exercise = TRUE)

params <- parameterize_gas_pbt(chem.cas="80-05-7")
solve_gas_pbt(parameters=params)

# Oral dose with exhalation as a route of elimination:
out <- solve_gas_pbt(chem.name = 'bisphenol a', exp.conc = 0, dose=100,
input.units="mg/kg")

# Note that different model compartments for this model have different units
# and that the final units can be controlled with the output.units argument:
head(solve_gas_pbt(chem.name="lindane"))
# Convert all compartment units to mg/L:
head(solve_gas_pbt(chem.name="lindane",output.units="mg/L"))
# Convert just the plasma to mg/L:
head(solve_gas_pbt(chem.name="lindane",output.units=list(Cplasma="mg/L")))
```

solve_model

Solve_model

Description

solve_model is designed to accept systematized metadata (provided by the model.list defined in the modelinfo files) for a given toxicokinetic model, including names of variables, parameterization functions, and key units, and use it along with chemical information to prepare an ode system for numerical solution over time of the amounts or concentrations of chemical in different bodily compartments of a given species (either "Rat", "Rabbit", "Dog", "Mouse", or default "Human").

Usage

```
solve_model(
  chem.name = NULL,
  chem.cas = NULL,
  dtxsid = NULL,
  times = NULL,
  parameters = NULL,
  model = NULL,
  route = "oral",
  dosing = NULL,
  days = 10,
  tsteps = 4,
  initial.values = NULL,
  initial.value.units = NULL,
  plots = FALSE,
  monitor.vars = NULL,
  suppress.messages = FALSE,
  species = "Human",
  input.units = "mg/kg",
  output.units = NULL,
  method = "lsoda",
  rtol = 1e-08,
  atol = 1e-12,
  recalc.blood2plasma = FALSE,
  recalc.clearance = FALSE,
  adjusted.funbound.plasma = TRUE,
  minimum.funbound.plasma = 1e-04,
  parameterize.arg.list = list(default.to.human = FALSE, clint.pvalue.threshold = 0.05,
    restrictive.clearance = TRUE, regression = TRUE),
  ...
)
```

Arguments

chem.name	Either the chemical name, CAS number, or the parameters must be specified.
chem.cas	Either the chemical name, CAS number, or the parameters must be specified.
dtxsid	EPA's DSSTox Structure ID (http://comptox.epa.gov/dashboard) the chemical must be identified by either CAS, name, or DTXSIDs

times	Optional time sequence for specified number of days. Dosing sequence begins at the beginning of times.
parameters	List of chemical parameters, as output by parameterize_pbt function. Overrides chem.name and chem.cas.
model	Specified model to use in simulation: "pbt", "3compartment", "3compartmentss", "1compartment", "schmitt", ...
route	String specification of route of exposure for simulation: "oral", "iv", "inhalation", ...
dosing	List of dosing metrics used in simulation, which includes the namesake entries of a model's associated dosing.params. In the case of most htk models, these should include "initial.dose", "doses.per.day", "daily.dose", and "dosing.matrix". The "dosing.matrix" is used for more precise dose regimen specification, and is a matrix consisting of two columns or rows named "time" and "dose" containing the time and amount of each dose. If none of the namesake entries of the dosing list is set to a non-NULL value, solve_model uses a default dose of 1 mg/kg BW along with the dose type (add/multiply) specified for a given route (e.g. add the dose to gut lumen for oral route)
days	Simulated period. Default 10 days.
tsteps	The number of time steps per hour. Default of 4.
initial.values	Vector of numeric values containing the initial concentrations or amounts of the chemical in specified tissues with units corresponding to those specified for the model outputs. Default values are zero.
initial.value.units	Vector of character strings containing the units corresponding to 'initial.values' specified for the model outputs. Default is assuming the units match expected compartment units for the model.
plots	Plots all outputs if true.
monitor.vars	Which variables are returned as a function of time. Default values of NULL looks up variables specified in modelinfo_MODEL.R
suppress.messages	Whether or not the output messages are suppressed.
species	Species desired (models have been designed to be parameterized for some subset of the following species: "Rat", "Rabbit", "Dog", "Mouse", or default "Human").
input.units	Input units of interest assigned to dosing. Defaults to mg/kg BW, in line with the default dosing scheme of a one-time dose of 1 mg/kg in which no other dosing parameters are specified.
output.units	Output units of interest for the compiled components. Defaults to NULL, and will provide values in model units if unspecified.
method	Method used by integrator (deSolve).
rtol	Argument passed to integrator (deSolve).
atol	Argument passed to integrator (deSolve).
recalc.blood2plasma	Recalculates the ratio of the amount of chemical in the blood to plasma using the input parameters, calculated with hematocrit, Funbound.plasma, and Krbc2pu.
recalc.clearance	Recalculates the the hepatic clearance (Clmetabolism) with new million.cells.per.g liver parameter.

<code>adjusted.funbound.plasma</code>	Uses <code>adjusted.funbound.plasma</code> when set to TRUE along with partition coefficients calculated with this value.
<code>minimum.funbound.plasma</code>	Monte Carlo draws less than this value are set equal to this value (default is 0.0001 – half the lowest measured <code>Fup</code> in our dataset)
<code>parameterize.arg.list</code>	Additional parameterized passed to the model parameterization function.
<code>...</code>	Additional arguments passed to the integrator.
<code>default.to.human</code>	Substitutes missing animal values with human values if true (hepatic intrinsic clearance or fraction of unbound plasma).
<code>regression</code>	Whether or not to use the regressions in calculating partition coefficients.
<code>restrictive.clearance</code>	Protein binding not taken into account (set to 1) in liver clearance if FALSE.

Details

Dosing values with certain acceptable associated `input.units` (like mg/kg BW) are configured to undergo a unit conversion. All model simulations are intended to run with units as specified by "`compartment.units`" in the `model.list` (as defined by the `modelinfo` files).

The 'dosing' argument includes all parameters needed to describe exposure in terms of route of administration, frequency, and quantity short of scenarios that require use of a more precise forcing function. If the dosing argument's namesake entries are left NULL, `solve_model` defaults to a single-time dose of 1 mg/kg BW according to the given dosing route and associated type (either add/multiply, for example we typically add a dose to gut lumen when oral route is specified).

AUC is the area under the curve of the plasma concentration.

Model parameters are named according to the following convention:

prefix	suffix	Meaning	units
K		Partition coefficient for tissue to free plasma \ tab	unitless
V		Volume	L
Q		Flow	L/h
k		Rate	1/h
	c	Parameter is proportional to body weight	1 / kg for volumes and 1/kg^(3/4) for flows

When species is specified but chemical-specific in vitro data are not available, the function uses the appropriate physiological data (volumes and flows) but `default.to.human = TRUE` must be used to substitute human fraction unbound, partition coefficients, and intrinsic hepatic clearance.

Value

A matrix of class `deSolve` with a column for time(in days), each compartment, the area under the curve, and plasma concentration and a row for each time point.

solve_pbtok

Solve_PBTk

Description

This function solves for the amounts or concentrations in uM of a chemical in different tissues as functions of time based on the dose and dosing frequency.

Usage

```
solve_pbtok(  
  chem.name = NULL,  
  chem.cas = NULL,  
  dtxsid = NULL,  
  times = NULL,  
  parameters = NULL,  
  days = 10,  
  tsteps = 4,  
  daily.dose = NULL,  
  dose = NULL,  
  doses.per.day = NULL,  
  initial.values = NULL,  
  plots = FALSE,  
  suppress.messages = FALSE,  
  species = "Human",  
  iv.dose = FALSE,  
  input.units = "mg/kg",  
  output.units = NULL,  
  method = "lsoda",  
  rtol = 1e-08,  
  atol = 1e-12,  
  default.to.human = FALSE,  
  recalc.blood2plasma = FALSE,  
  recalc.clearance = FALSE,  
  dosing.matrix = NULL,  
  adjusted.funbound.plasma = TRUE,  
  regression = TRUE,  
  restrictive.clearance = TRUE,  
  minimum.funbound.plasma = 1e-04,  
  monitor.vars = NULL,  
  ...  
)
```

Arguments

chem.name Either the chemical name, CAS number, or the parameters must be specified.

chem.cas	Either the chemical name, CAS number, or the parameters must be specified.
dtxsid	EPA's DSSTox Structure ID (https://comptox.epa.gov/dashboard) the chemical must be identified by either CAS, name, or DTXIDs
times	Optional time sequence for specified number of days. Dosing sequence begins at the beginning of times.
parameters	Chemical parameters from parameterize_pbt function, overrides chem.name and chem.cas.
days	Length of the simulation.
tsteps	The number of time steps per hour.
daily.dose	Total daily dose, defaults to mg/kg BW.
dose	Amount of a single dose, defaults to mg/kg BW.
doses.per.day	Number of doses per day.
initial.values	Vector containing the initial concentrations or amounts of the chemical in specified tissues with units corresponding to output.units. Defaults are zero.
plots	Plots all outputs if true.
suppress.messages	Whether or not the output message is suppressed.
species	Species desired (either "Rat", "Rabbit", "Dog", "Mouse", or default "Human").
iv.dose	Simulates a single i.v. dose if true.
input.units	Input units of interest assigned to dosing, defaults to mg/kg BW
output.units	A named vector of output units expected for the model results. Default, NULL, returns model results in units specified in the 'modelinfo' file. See table below for details.
method	Method used by integrator (deSolve).
rtol	Argument passed to integrator (deSolve).
atol	Argument passed to integrator (deSolve).
default.to.human	Substitutes missing animal values with human values if true (hepatic intrinsic clearance or fraction of unbound plasma).
recalc.blood2plasma	Recalculates the ratio of the amount of chemical in the blood to plasma using the input parameters, calculated with hematocrit, Funbound.plasma, and Krbc2pu.
recalc.clearance	Recalculates the the hepatic clearance (Clmetabolism) with new million.cells.per.g liver parameter.
dosing.matrix	Vector of dosing times or a matrix consisting of two columns or rows named "dose" and "time" containing the time and amount, in mg/kg BW, of each dose.
adjusted.Funbound.plasma	Uses adjusted Funbound.plasma when set to TRUE along with partition coefficients calculated with this value.
regression	Whether or not to use the regressions in calculating partition coefficients.
restrictive.clearance	Protein binding not taken into account (set to 1) in liver clearance if FALSE.
minimum.Funbound.plasma	Monte Carlo draws less than this value are set equal to this value (default is 0.0001 – half the lowest measured Fup in our dataset).

`monitor.vars` Which variables are returned as a function of time. The default value of NULL provides "Cgut", "Cliver", "Cven", "Clung", "Cart", "Crest", "Ckidney", "Cplasma", "Atubules", "Ametabolized", and "AUC"

... Additional arguments passed to the integrator.

Details

Note that the model parameters have units of hours while the model output is in days.

Default NULL value for `doses.per.day` solves for a single dose.

The compartments used in this model are the gutlumen, gut, liver, kidneys, veins, arteries, lungs, and the rest of the body.

The extra compartments include the amounts or concentrations metabolized by the liver and excreted by the kidneys through the tubules.

AUC is the area under the curve of the plasma concentration.

Model Figure

altalt

When species is specified as rabbit, dog, or mouse, the function uses the appropriate physiological data(volumes and flows) but substitutes human fraction unbound, partition coefficients, and intrinsic hepatic clearance.

Value

A matrix of class `deSolve` with a column for time(in days), each compartment, the area under the curve, and plasma concentration and a row for each time point.

Examples

```
# Multiple doses per day:
head(solve_pbt(
  chem.name='Bisphenol-A',
  daily.dose=.5,
  days=5,
  doses.per.day=2,
  tsteps=2))

# Starting with an initial concentration:
out <- solve_pbt(
  chem.name='bisphenola',
  dose=0,
  output.units="mg/L",
  initial.values=c(Agut=200))

# Working with parameters (rather than having solve_pbt retrieve them):
params <- parameterize_pbt(chem.cas="80-05-7")
head(solve_pbt(parameters=params))

# We can change the parameters given to us by parameterize_pbt:
params <- parameterize_pbt(dtcsid="DTXSID4020406", species = "rat")
params["Funbound.plasma"] <- 0.1
out <- solve_pbt(parameters=params)

# A fifty day simulation:
out <- solve_pbt(
  chem.name = "Bisphenol A",
  days = 50,
  daily.dose=1,
  doses.per.day = 3)
plot.data <- as.data.frame(out)
css <- calc_analytic_css(chem.name = "Bisphenol A")

library("ggplot2")
c.vs.t <- ggplot(plot.data, aes(time, Cplasma)) +
  geom_line() +
  geom_hline(yintercept = css) +
  ylab("Plasma Concentration (uM)") +
  xlab("Day") +
  theme(
    axis.text = element_text(size = 16),
    axis.title = element_text(size = 16),
    plot.title = element_text(size = 17)) +
  ggtitle("Bisphenol A")
print(c.vs.t)
```

spleen_mass_children *Predict spleen mass for children*

Description

For individuals under 18, predict the spleen mass from height, weight, and gender, using equations from Ogiu et al. (1997)

Usage

```
spleen_mass_children(height, weight, gender)
```

Arguments

height	Vector of heights in cm.
weight	Vector of weights in kg.
gender	Vector of genders (either 'Male' or 'Female').

Value

A vector of spleen masses in kg.

tissue.data	<i>Tissue composition and species-specific physiology parameters</i>
-------------	--

Description

This data set contains values from Schmitt (2008) and Ruark et al. (2014) describing the composition of specific tissues and from Birnbaum et al. (1994) describing volumes of and blood flows to those tissues, allowing parameterization of toxicokinetic models for human, mouse, rat, dog, or rabbit. Tissue volumes were calculated by converting the fractional mass of each tissue with its density (both from ICRP), lumping the remaining tissues into the rest-of-body, excluding the mass of the gastrointestinal contents

Usage

tissue.data

Format

A data.frame containing 13 rows and 20 columns.

tissue_scale	<i>Allometric scaling.</i>
--------------	----------------------------

Description

Allometrically scale a tissue mass or flow based on $\text{height}^{3/4}$.

Usage

```
tissue_scale(height_ref, height_indiv, tissue_mean_ref)
```

Arguments

height_ref	Reference height in cm.
height_indiv	Individual height in cm.
tissue_mean_ref	Reference tissue mass or flow.

Value

Allometrically scaled tissue mass or flow, in the same units as `tissue_mean_ref`.

wambaugh2019.tox21	<i>Tox21 2015 Active Hit Calls (EPA)</i>
--------------------	--

Description

The ToxCast and Tox21 research programs employ batteries of high-throughput assays to assess chemical bioactivity in vitro. Not every chemical is tested through every assay. Most assays are conducted in concentration response, and each corresponding assay endpoint is analyzed statistically to determine if there is a concentration-dependent response or "hit" using the ToxCast Pipeline. Most assay endpoint-chemical combinations are non-responsive. Here, only the hits are treated as potential indicators of bioactivity. This bioactivity does not have a direct toxicological interpretation. The October 2015 release (invitrodb_v2) of the ToxCast and Tox21 data were used for this analysis. This object contains just the chemicals in Wambaugh et al. (2019) and only the quantiles across all assays for the ACC.
