

Package ‘ti’

February 10, 2026

Title Time Intelligence and Customer Segmentation for Financial Analysis

Description Calculate time intelligence metrics for financial planning and analysis. 'ti' provides functions for period-over-period comparisons (year-over-year, month-over-month), period-to-date calculations (YTD, MTD, QTD), and customer segmentation (ABC analysis, cohorts). Supports standard and retail calendars (4-4-5, 4-5-4, 5-4-4) with both in-memory and database backends via 'dbplyr'.

Version 4.0.0

abc	<i>ABC classification function</i>
-----	------------------------------------

Description

- For your group variable, `abc()` will categorize which groups make up what proportion of the totals according to the `category_values` that you have entered
- The function returns a segment object which prints out the execution steps and actions that it will take to categorize your data
- Use `calculate` to return the results

Usage

```
abc(.data, category_values, .value)
```

Arguments

<code>.data</code>	tibble or dbi object (either grouped or ungrouped)
<code>category_values</code>	vector of break points between 0 and 1
<code>.value</code>	optional: if left blank, <code>abc()</code> will use the number of rows per group to categorize, alternatively you can pass a column name to categorize

Details

- This function is helpful to understand which groups of make up what proportion of the cumulative contribution
- If you do not provide a .value then it will count the transactions per group, if you provide .value then it will `sum()` the .value per group
- The function creates a segment object, which pre-processes the data into its components

Value

abc object

Examples

```
contoso::sales |>
  dplyr::group_by(product_key) |>
  abc(c(.1,.5,.7,.96,1), .value = margin)
```

atd	<i>All period-to-date</i>
-----	---------------------------

Description

This calculates the all-time cumulative sum of targeted value using a standard or 5-5-4 calendar respecting any groups that are passed through with `dplyr::group_by()`
Use `calculate` to return the results

Usage

```
atd(.data, .date, .value, calendar_type = "standard", fiscal_year_start = 1)
```

Arguments

.data	tibble or dbi object (either grouped or ungrouped)
.date	the date column to group by
.value	the value column to summarize
calendar_type	select either 'standard', '445', '454', or '544' calendar, see 'Details' for additional information
fiscal_year_start	integer 1-12, the month the fiscal year starts nearest to (default 1 = January). Only used with retail calendars ('445', '454', '544').

Details

- This function creates a complete calendar object that fills in any missing days, weeks, months, quarters, or years
- If you provide a grouped object with `dplyr::group_by()`, it will generate a complete calendar for each group
- The function creates a `ti` object, which pre-processes the data and arguments for further downstream functions

standard calendar

- The standard calendar splits the year into 12 months (with 28–31 days each) and uses a 7-day week
- It automatically accounts for leap years every four years to match the Gregorian calendar

5-5-4 calendar

- The 5-5-4 calendar divides the fiscal year into 52 weeks (occasionally 53), organizing each quarter into two 5-week periods and one 4-week period.
- This system is commonly used in retail and financial reporting

Value

`ti` object

Examples

```
atd(contoso::sales, .date=order_date, .value=quantity, calendar_type="standard")
```

augment_standard_calendar

Add Comprehensive Date-Based Attributes to a DBI lazy frame or tibble object

Description

This function takes a data frame and a date column and generates a wide set of derived date attributes. These include start/end dates for year, quarter, month, and week; day-of-week indicators; completed and remaining days in each time unit; and additional convenience variables such as weekend indicators.

It is designed for time-based feature engineering and is useful in reporting, forecasting, time-series modeling, and data enrichment workflows.

Usage

```
augment_standard_calendar(.data, .date)
```

Arguments

<code>.data</code>	A data frame or tibble containing at least one date column.
<code>.date</code>	A column containing Date values, passed using tidy-eval (e.g., <code>{{ date_col }}</code>).

Details

The function creates the following groups of attributes:

1. Start and end dates

- `year_start_date`, `year_end_date`
- `quarter_start_date`, `quarter_end_date`
- `month_start_date`, `month_end_date`
- `week_start_date`, `week_end_date`

2. Day-of-week fields

- `day_of_week` – numeric day of the week (1–7)
- `day_of_week_label` – ordered factor label (e.g., Mon, Tue, ...)

3. Duration fields

- `days_in_year` – total days in the year interval
- `days_in_quarter` – total days in the quarter interval
- `days_in_month` – total days in the month

4. Completed/remaining days

- `days_complete_in_week`, `days_remaining_in_week`
- `days_complete_in_month`, `days_remaining_in_month`
- `days_complete_in_quarter`, `days_remaining_in_quarter`
- `days_complete_in_year`, `days_remaining_in_year`

5. Miscellaneous

- `weekend_indicator` – equals 1 if Saturday or Sunday; otherwise 0

All date-derived fields ending in `_date` are coerced to class Date.

Value

A dbi or tibble containing the original data along with all generated date-based attributes.

calculate	<i>Execute time-intelligence or segments class objects to return the underlying transformed table</i>
-----------	---

Description

The `calculate()` function takes an object created by a time function (like `ytd()`, `mtd()`, or `qtd()`) or a segment function (like `cohort()` or `abc()`) and executes the underlying transformation logic. It translates the function blueprint into an actionable query, returning the final data table.

Arguments

x ti object

Details

The TI and segment functions in **ti**—such as `ytd()` or `cohort()` and others—are designed to be **lazy and database-friendly**. They do not perform the heavy data transformation immediately. Instead, they return a blueprint object (of class `ti`, `segment_abc` or `segment_cohort`) that contains all the parameters and logic needed for the calculation.

`calculate()` serves as the **execution engine**.

When called, it interprets the blueprint and generates optimized R code or SQL code (using the `dbplyr` package) that is then executed efficiently on the data source, whether it's an in-memory tibble or a remote database backend (like `duckdb` or `snowflake`). This approach minimizes data transfer and improves performance for large datasets.

The resulting table will be sorted by the relevant date column to ensure the correct temporal ordering of the calculated metrics.

Value

dbi object

Examples

```
x <- ytd(contoso::sales, .date=order_date, .value=quantity, calendar_type="standard")
calculate(x)
```

cohort	<i>Cohort Analysis</i>
--------	------------------------

Description

Database-friendly cohort analysis function. A remake of <https://github.com/PeerChristensen/cohorts>, combining cohort_table_month, cohort_table_year, and cohort_table_day into a single package. Rewritten for database compatibility and tested with Snowflake and DuckDB.

Usage

```
cohort(.data, .date, .value, time_unit = "month", period_label = FALSE)
```

Arguments

.data	tibble or dbi object
.date	date column
.value	id column
time_unit	do you want summarize the date column to 'day', 'week', 'month','quarter' or 'year'
period_label	do you want period labels or the dates c(TRUE , FALSE)

Details

- Groups your .value column by shared time attributes from the .date column.
- Assigns each member to a cohort based on their first entry in .date.
- Aggregates the cohort by the time_unit argument (day, week, month, quarter, or year).
- Computes the distinct count of each cohort member over time.

Value

segment object

dod	<i>Current period day over previous period day</i>
-----	--

Description

This calculates the daily value compared to the previous day's value using a standard or 5-5-4 calendar respecting any groups that are passed through with `dplyr::group_by()`
Use `calculate` to return the results

Usage

```
dod(
  .data,
  .date,
  .value,
  calendar_type = "standard",
  lag_n = 1,
  fiscal_year_start = 1
)
```

Arguments

<code>.data</code>	tibble or dbi object (either grouped or ungrouped)
<code>.date</code>	the date column to group by
<code>.value</code>	the value column to summarize
<code>calendar_type</code>	select either 'standard', '445', '454', or '544' calendar, see 'Details' for additional information
<code>lag_n</code>	the number of periods to lag
<code>fiscal_year_start</code>	integer 1-12, the month the fiscal year starts nearest to (default 1 = January). Only used with retail calendars ('445', '454', '544').

Details

- This function creates a complete calendar object that fills in any missing days, weeks, months, quarters, or years
- If you provide a grouped object with `dplyr::group_by()`, it will generate a complete calendar for each group
- The function creates a `ti` object, which pre-processes the data and arguments for further downstream functions

standard calendar

- The standard calendar splits the year into 12 months (with 28–31 days each) and uses a 7-day week
- It automatically accounts for leap years every four years to match the Gregorian calendar

5-5-4 calendar

- The 5-5-4 calendar divides the fiscal year into 52 weeks (occasionally 53), organizing each quarter into two 5-week periods and one 4-week period.
- This system is commonly used in retail and financial reporting

Value

`ti` object

```

mom

Current full period month over previous full period month

Description

This calculates the monthly cumulative sum of targeted value using a standard or 5-5-4 calendar respecting any groups that are passed through with [dplyr::group_by\(\)](#)

Use [calculate](#) to return the results

Usage

```
mom(
  .data,
  .date,
  .value,
  calendar_type = "standard",
  lag_n = 1,
  fiscal_year_start = 1
)
```

Arguments

<code>.data</code>	tibble or dbi object (either grouped or ungrouped)
<code>.date</code>	the date column to group by
<code>.value</code>	the value column to summarize
<code>calendar_type</code>	select either 'standard', '445', '454', or '544' calendar, see 'Details' for additional information

mom(contoso::sales, .date=order_date, .value=quantity, calendar_type='standard', lag_n=1)
```

momtd	<i>Current period month to date compared to previous period month-to-date</i>
-------	---

Description

This calculates the monthly cumulative sum of targeted value using a standard or 5-5-4 calendar respecting any groups that are passed through with `dplyr::group_by()`

Use `calculate` to return the results

Usage

```
momtd(
  .data,
  .date,
  .value,
  calendar_type = "standard",
  lag_n = 1,
  fiscal_year_start = 1
)
```

Arguments

<code>.data</code>	tibble or dbi object (either grouped or ungrouped)
<code>.date</code>	the date column to group by
<code>.value</code>	the value column to summarize
<code>calendar_type</code>	select either 'standard', '445', '454', or '544' calendar, see 'Details' for additional information

```

mtdopm

Current month-to-date over full previous period month

Description

This calculates the monthly cumulative sum of targeted value using a standard or 5-5-4 calendar respecting any groups that are passed through with [dplyr::group_by\(\)](#)

Use [calculate](#) to return the results

Usage

```
mtdopm(
  .data,
  .date,
  .value,
  calendar_type = "standard",
  lag_n = 1,
  fiscal_year_start = 1
)
```

Arguments

<code>.data</code>	tibble or dbi object (either grouped or ungrouped)
<code>.date</code>	the date column to group by
<code>.value</code>	the value column to summarize
<code>calendar_type</code>	select either 'standard', '445', '454', or '544' calendar, see 'Details' for additional information
<code>lag_n</code>	the number of periods to lag
<code>fiscal_year_start</code>	integer 1-12, the month the fiscal year starts nearest to (default 1 = January). Only used with retail calendars ('445', '454', '544').

Details

- This function creates a complete calendar object that fills in any missing days, weeks, months, quarters, or years

```
mtdopm(contoso::sales, .date=order_date, .value=quantity, calendar_type="standard", lag_n=1)
```

pmtd	<i>Previous period month-to-date</i>
------	--------------------------------------

Description

This calculates the monthly cumulative sum of targeted value using a standard or 5-5-4 calendar respecting any groups that are passed through with `dplyr::group_by()`

Use `calculate` to return the results

Usage

```
pmtd(
  .data,
  .date,
  .value,
  calendar_type = "standard",
  lag_n = 1,
  fiscal_year_start = 1
)
```

Arguments

<code>.data</code>	tibble or dbi object (either grouped or ungrouped)
<code>.date</code>	the date column to group by
<code>.value</code>	the value column to summarize
<code>calendar_type</code>	select either 'standard', '445', '454', or '544' calendar, see 'Details' for additional information

pqtd(contoso::sales, .date=order_date, .value=quantity, calendar_type="standard", lag_n=1)
```

pwtd	<i>Previous period week-to-date</i>
------	-------------------------------------

Description

This calculates the weekly cumulative sum of targeted value for the previous week using a standard or 5-5-4 calendar respecting any groups that are passed through with `dplyr::group_by()`

Use `calculate` to return the results

Usage

```
pwtd(
  .data,
  .date,
  .value,
  calendar_type = "standard",
  lag_n = 1,
  fiscal_year_start = 1
)
```

Arguments

<code>.data</code>	tibble or dbi object (either grouped or ungrouped)
<code>.date</code>	the date column to group by
<code>.value</code>	the value column to summarize
<code>calendar_type</code>	select either 'standard', '445', '454', or '544' calendar, see 'Details' for additional information
<code>lag_n</code>	the number of periods to lag
<code>fiscal_year_start</code>	integer 1-12, the month the fiscal year starts nearest to (default 1 = January). Only used with retail calendars ('445', '454', '544').

Examples

```
pwtd(contoso::sales, .date=order_date, .value=quantity, calendar_type="standard", lag_n=1)
```

pytd

Previous period year-to-date

Description

- For each group, [pytd\(\)](#) will create the running annual sum of a value based on the calendar type for the previous year compared to the current year calendar date
- If no period exists, it will return NA
- The function returns a ti object which prints out the summary of steps and actions that will take to create the calendar table and calculations
- Use [calculate](#) to return the results

Usage

```
pytd(
  .data,
  .date,
  .value,
  calendar_type = "standard",
  lag_n,
  fiscal_year_start = 1
)
```

Arguments

<code>.data</code>	tibble or dbi object (either grouped or ungrouped)
<code>.date</code>	the date column to group by
<code>.value</code>	the value column to summarize
<code>calendar_type</code>	select either 'standard', '445', '454', or '544' calendar, see 'Details' for additional information
<code>lag_n</code>	the number of periods to lag
<code>fiscal_year_start</code>	integer 1-12, the month the fiscal year starts nearest to (default 1 = January). Only used with retail calendars ('445', '454', '544').

Details

- This function creates a complete calendar object that fills in any missing days, weeks, months, quarters, or years
- If you provide a grouped object with `dplyr::group_by()`, it will generate a complete calendar for each group
- The function creates a `ti` object, which pre-processes the data and arguments for further downstream functions

standard calendar

- The standard calendar splits the year into 12 months (with 28–31 days each) and uses a 7-day week
- It automatically accounts for leap years every four years to match the Gregorian calendar

5-5-4 calendar

- The 5-5-4 calendar divides the fiscal year into 52 weeks (occasionally 53), organizing each quarter into two 5-week periods and one 4-week period.
- This system is commonly used in retail and financial reporting

Value

`ti` object

```

qoq

*Current full period quarter over previous full period quarter***Description**

- This calculates the full quarter value compared to the previous quarter value respecting any groups that are passed through with `dplyr::group_by()`
- Use `calculate` to return the results

Usage

```
qoq(
  .data,
  .date,
  .value,
  calendar_type = "standard",
  lag_n = 1,
  fiscal_year_start = 1
)
```

Arguments

<code>.data</code>	tibble or dbi object (either grouped or ungrouped)
<code>.date</code>	the date column to group by
<code>.value</code>	the value column to summarize
<code>calendar_type</code>	select either 'standard', '445', '454', or '544' calendar, see 'Details' for additional information

Examples

```
ytd(contoso::sales,.date=order_date,.value=quantity,calendar_type="standard")
```

ytdopy

Current period year-to-date compared to full previous period

Description

- This calculates the full year value compared to the previous year value using a standard or 5-5-4 calendar respecting any groups that are passed through with [dplyr::group_by\(\)](#)
- Use [calculate](#) to return the results

Usage

```
ytdopy(
  .data,
  .date,
  .value,
  calendar_type = "standard",
  lag_n = 1,
  fiscal_year_start = 1
)
```

Arguments

<code>.data</code>	tibble or dbi object (either grouped or ungrouped)
<code>.date</code>	the date column to group by
<code>.value</code>	the value column to summarize
<code>calendar_type</code>	select either 'standard', '445', '454', or '544' calendar, see 'Details' for additional information
<code>lag_n</code>	the number of periods to lag
<code>fiscal_year_start</code>	integer 1-12, the month the fiscal year starts nearest to (default 1 = January). Only used with retail calendars ('445', '454', '544').

Details

- This function creates a complete calendar object that fills in any missing days, weeks, months, quarters, or years
- If you provide a grouped object with `dplyr::group_by()`, it will generate a complete calendar for each group
- The function creates a `ti` object, which pre-processes the data and arguments for further downstream functions

standard calendar

- The standard calendar splits the year into 12 months (with 28–31 days each) and uses a 7-day week
- It automatically accounts for leap years every four years to match the Gregorian calendar

5-5-4 calendar

- The 5-5-4 calendar divides the fiscal year into 52 weeks (occasionally 53), organizing each quarter into two 5-week periods and one 4-week period.
- This system is commonly used in retail and financial reporting

Value

`ti` object
